

# SPLITTING THE RELATIVE ASSEMBLY MAP, NIL-TERMS AND INVOLUTIONS

WOLFGANG LÜCK AND WOLFGANG STEIMLE

ABSTRACT. We show that the relative Farrell-Jones assembly map from the family of finite subgroups to the family of virtually cyclic subgroups for algebraic  $K$ -theory is split injective in the setting where the coefficients are additive categories with group action. This generalizes a result of Bartels for rings as coefficients. We give an explicit description of the relative term. This enables us to show that it vanishes rationally if we take coefficients in a regular ring. Moreover, it is, considered as a  $\mathbb{Z}[\mathbb{Z}/2]$ -module by the involution coming from taking dual modules, an extended module and in particular all its Tate cohomology groups vanish, provided that the infinite virtually cyclic subgroups of type I of  $G$  are orientable. The latter condition is for instance satisfied for torsionfree hyperbolic groups.

## INTRODUCTION

0.1. **Motivation.** The  $K$ -theoretic Farrell-Jones Conjecture for a group  $G$  and a ring  $R$  predicts that the assembly map

$$\text{asmb}_n: H_n^G(\underline{EG}; \mathbf{K}_R) \rightarrow H_n^G(G/G; \mathbf{K}_R) = K_n(RG)$$

is an isomorphism for all  $n \in \mathbb{Z}$ . Here  $\underline{EG} = E_{\mathcal{VC}}(G)$  is the classifying space for the family  $\mathcal{VC}$  of virtually cyclic subgroups and  $H_n^G(-; \mathbf{K}_R^G)$  is the  $G$ -homology theory associated to a specific covariant functor  $\mathbf{K}_R^G$  from the orbit category  $\text{Or}(G)$  to the category of spectra  $\text{Spectra}$ . It satisfies  $H_n^G(G/H; \mathbf{K}_R^G) = \pi_n(\mathbf{K}^G(G/H)) = K_n(RH)$  for any subgroup  $H \subseteq G$  and  $n \in \mathbb{Z}$ . The assembly map is induced by the projection  $\underline{EG} \rightarrow G/G$ . The original source for the Farrell-Jones Conjecture is the paper by Farrell-Jones [7, 1.6 on page 257 and 1.7 on page 262]. More information about the Farrell-Jones Conjecture and the classifying spaces for families can be found for instance in the survey articles [16] and [18].

Let  $\underline{EG} = E_{\mathcal{Fin}}(G)$  be the classifying space for the family  $\mathcal{Fin}$  of finite subgroups, sometimes also called the classifying space for proper  $G$ -actions. The  $G$ -map  $\underline{EG} \rightarrow \underline{EG}$ , which is unique up to  $G$ -homotopy, induces a so-called relative assembly map

$$\overline{\text{asmb}}_n: H_n^G(\underline{EG}; \mathbf{K}_R) \rightarrow H_n^G(\underline{EG}; \mathbf{K}_R).$$

The main result of a paper by Bartels [3, Theorem 1.3] says that  $\overline{\text{asmb}}_n$  is split injective for all  $n \in \mathbb{Z}$ .

In this paper we improve on this result in two different directions: First we generalize from the context of rings  $R$  to the context of additive categories  $\mathcal{A}$  with  $G$ -action. This improvement allows to consider twisted group rings and involutions twisted by an orientation homomorphism  $G \rightarrow \{\pm 1\}$ ; moreover one obtains better inheritance properties and gets fibered versions for free.

*Date:* September, 2015.

*2000 Mathematics Subject Classification.* 18F25, 19A31, 19B28, 19D35.

*Key words and phrases.* splitting relative  $K$ -theoretic assembly maps, rational vanishing and Tate cohomology of the relative Nil-term.

Secondly, we give an explicit description of the relative term in terms of so-called NK-spectra. This becomes relevant for instance in the study of the involution on the cokernel of the relative assembly map induced by an involution of  $\mathcal{A}$ . In more detail, we prove:

**0.2. Splitting the relative assembly map.** Our main splitting result is

**Theorem 0.1** (Splitting the  $K$ -theoretic assembly map from  $\mathcal{F}in$  to  $\mathcal{V}C$ ). *Let  $G$  be a group and let  $\mathcal{A}$  be an additive  $G$ -category. Let  $n$  be any integer.*

*Then the relative  $K$ -theoretic assembly map*

$$\overline{\text{asmb}}_n: H_n^G(\underline{EG}; \mathbf{K}_{\mathcal{A}}^G) \rightarrow H_n^G(\underline{EG}; \mathbf{K}_{\mathcal{A}}^G)$$

*is split injective. In particular we obtain a natural splitting*

$$H_n^G(\underline{EG}; \mathbf{K}_{\mathcal{A}}^G) \xrightarrow{\cong} H_n^G(\underline{EG}; \mathbf{K}_{\mathcal{A}}^G) \oplus H_n^G(\underline{EG} \rightarrow \underline{EG}; \mathbf{K}_{\mathcal{A}}^G).$$

*Moreover, there exists an  $\text{Or}(G)$ -spectrum  $\mathbf{NK}_{\mathcal{A}}^G$  and a natural isomorphism*

$$H_n^G(\underline{EG} \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G) \xrightarrow{\cong} H_n^G(\underline{EG} \rightarrow \underline{EG}; \mathbf{K}_{\mathcal{A}}^G).$$

Here  $E_{\mathcal{V}C_I}(G)$  denotes the classifying space for the family of virtually cyclic subgroups of type I, see section 1. The proof will appear in Section 7. The point is that, instead of considering  $\mathbf{K}_R^G$  for a ring  $R$ , we can treat the more general setup  $\mathbf{K}_{\mathcal{A}}^G$  for an additive  $G$ -category  $\mathcal{A}$ , as explained in [1] and [2]. (One obtains the case of a ring  $R$  back if one considers for  $\mathcal{A}$  the category  $R$ -FGF of finitely generated free  $R$ -modules with the trivial  $G$ -action. Notice that we tacitly always apply idempotent completion to the additive categories before taking  $K$ -theory.) Whereas in [3, Theorem 1.3] just a splitting is constructed, we construct explicit  $\text{Or}(G)$ -spectra  $\mathbf{NK}_{\mathcal{A}}^G$  and identify the relative terms. This is crucial for the following results.

**0.3. Involutions and vanishing of Tate cohomology.** We will prove in Subsection 8.3

**Theorem 0.2** (The relative term is induced). *Let  $G$  be a group and let  $\mathcal{A}$  be an additive  $G$ -category with involution. Suppose that the virtually cyclic subgroups of type I of  $G$  are orientable (see Definition 8.5).*

*Then the  $\mathbb{Z}/2$ -module  $H_n(\underline{EG} \rightarrow \underline{EG}; \mathbf{K}_{\mathcal{A}}^G)$  is isomorphic to  $\mathbb{Z}[\mathbb{Z}/2] \otimes_{\mathbb{Z}} A$  for some  $\mathbb{Z}$ -module  $A$ .*

In [9] we will be interested in the conclusion of Theorem 0.2 that the Tate cohomology groups  $\widehat{H}^i(\mathbb{Z}/2, H_n(\underline{EG} \rightarrow \underline{EG}; \mathbf{K}_{\mathcal{A}}^G))$  vanish for all  $i, n \in \mathbb{Z}$  if the virtually cyclic subgroups of type I of  $G$  are orientable. In general the Tate spectrum of the involution on the Whitehead spectrum plays a role in the study of automorphisms of manifolds (see e.g. [26, section 4]).

**0.4. Rational vanishing of the relative term.**

**Theorem 0.3.** *Let  $G$  be a group and let  $R$  be a regular ring.*

*Then the relative assembly map*

$$\overline{\text{asmb}}_n: H_n^G(\underline{EG}; \mathbf{K}_R^G) \rightarrow H_n^G(\underline{EG}; \mathbf{K}_R^G)$$

*is rationally bijective for all  $n \in \mathbb{Z}$ .*

If  $R = \mathbb{Z}$  and  $n \leq -1$ , then the relative assembly map  $H_n^G(\underline{EG}; \mathbf{K}_{\mathbb{Z}}^G) \xrightarrow{\cong} H_n^G(\underline{EG}; \mathbf{K}_{\mathbb{Z}}^G)$  is an isomorphism by the results of [8].

Further computations of the relative term  $H_n^G(\underline{EG} \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G) \cong H_n^G(\underline{EG} \rightarrow \underline{EG}; \mathbf{K}_{\mathcal{A}}^G)$  are briefly discussed in Section 10.

**0.5. A fibered case.** In Section 11 we discuss a fibered situation which will be relevant for the forthcoming paper [9] and can be handled by our general treatment for additive  $G$ -categories.

**0.6. Acknowledgement.** This paper has been financially supported by the Leibniz-Award of the first author and the Center for Symmetry and Deformation at the University of Copenhagen. We thank the referee for her/his careful reading and useful comments.

## 1. VIRTUALLY CYCLIC GROUPS

A virtually cyclic group  $V$  is called of *type I* if it admits an epimorphism to the infinite cyclic group, and of *type II* if it admits an epimorphism onto the infinite dihedral group. The statements appearing in the next lemma are well-known, we insert a proof for the reader's convenience.

**Lemma 1.1.** *Let  $V$  be an infinite virtually cyclic group.*

- (i)  $V$  is either of type I or of type II;
- (ii) The following assertions are equivalent:
  - (a)  $V$  is of type I;
  - (b)  $H_1(V)$  is infinite;
  - (c)  $H_1(V)/\text{tors}(V)$  is infinite cyclic;
  - (d) The center of  $V$  is infinite;
- (iii) There exists a unique maximal normal finite subgroup  $K_V \subseteq V$ , i.e.,  $K_V$  is a finite normal subgroup and every normal finite subgroup of  $V$  is contained in  $K_V$ ;
- (iv) Let  $Q_V := V/K_V$ . Then we obtain a canonical exact sequence

$$1 \rightarrow K_V \xrightarrow{i_V} V \xrightarrow{p_V} Q_V \rightarrow 1.$$

Moreover,  $Q_V$  is infinite cyclic if and only if  $V$  is of type I and  $Q_V$  is isomorphic to the infinite dihedral group if and only if  $V$  is of type II;

- (v) Let  $f: V \rightarrow Q$  be any epimorphism onto the infinite cyclic group or onto the infinite dihedral group. Then the kernel of  $f$  agrees with  $K_V$ ;
- (vi) Let  $\phi: V \rightarrow W$  be a homomorphism of infinite virtually cyclic groups with infinite image. Then  $\phi$  maps  $K_V$  to  $K_W$  and we obtain the following canonical commutative diagram with exact rows

$$\begin{array}{ccccccccc} 1 & \longrightarrow & K_V & \xrightarrow{i_V} & V & \xrightarrow{p_V} & Q_V & \longrightarrow & 1 \\ & & \downarrow \phi_K & & \downarrow \phi & & \downarrow \phi_Q & & \\ 1 & \longrightarrow & K_W & \xrightarrow{i_W} & W & \xrightarrow{p_W} & Q_W & \longrightarrow & 1 \end{array}$$

with injective  $\phi_Q$ .

*Proof.* (ii) If  $V$  is of type I, then we obtain epimorphisms

$$V \rightarrow H_1(V) \rightarrow H_1(V)/\text{tors}(H_1(V)) \rightarrow \mathbb{Z}.$$

The kernel of  $V \rightarrow \mathbb{Z}$  is finite, since for an exact sequence  $1 \rightarrow \mathbb{Z} \xrightarrow{i} V \xrightarrow{q} H \rightarrow 1$  with finite  $H$  the composite of  $V \rightarrow \mathbb{Z}$  with  $i$  is injective and hence the restriction of  $q$  to the kernel of  $V \rightarrow \mathbb{Z}$  is injective. This implies that  $H_1(V)$  is infinite and  $H_1(V)/\text{tors}(H_1(V))$  is infinite cyclic. If  $H_1(V)/\text{tors}(H_1(V))$  is infinite cyclic or if  $H_1(V)$  is infinite, then  $H_1(V)$  surjects onto  $\mathbb{Z}$  hence so does  $V$ . This shows  $(ii)a \iff (ii)b \iff (ii)c$ .

Consider the exact sequence  $1 \rightarrow \text{cent}(V) \rightarrow V \rightarrow V/\text{cent}(V) \rightarrow 1$ , where  $\text{cent}(V)$  is the center of  $V$ . Suppose that  $\text{cent}(V)$  is infinite. Then  $V/\text{cent}(V)$

is finite and the Lyndon-Serre spectral yields an isomorphism  $\text{cent}(V) \otimes_{\mathbb{Z}} \mathbb{Q} \rightarrow H_1(V; \mathbb{Q})$ . Hence  $H_1(V)$  is infinite. This shows (ii)d  $\implies$  (ii)b.

Suppose that  $V$  is of type I. Choose an exact sequence  $1 \rightarrow K \rightarrow V \rightarrow \mathbb{Z} \rightarrow 1$  with finite  $K$ . Let  $v \in V$  be an element which is mapped to a generator of  $\mathbb{Z}$ . Then conjugation with  $v$  induces an automorphism of  $K$ . Since  $K$  is finite, we can find a natural number  $k$  such that conjugation with  $v^k$  induces the identity on  $K$ . One easily checks that  $v^k$  belongs to the center of  $V$  and  $v$  has infinite order. This shows (ii)a  $\implies$  (ii)d and finishes the proof of assertion (ii).

(iii) If  $K_1$  and  $K_2$  are two finite normal subgroups of  $V$ , then

$$K_1 \cdot K_2 := \{v \in V \mid \exists k_1 \in K_1 \text{ and } k_2 \in K_2 \text{ with } v = k_1 k_2\}$$

is a finite normal subgroup of  $V$ . Hence we are left to show that  $V$  has only finitely many different finite normal subgroups.

To see this, choose an exact sequence  $1 \rightarrow \mathbb{Z} \xrightarrow{i} V \xrightarrow{f} H \rightarrow 1$  for some finite group  $H$ . The map  $f$  induces a map from the finite normal subgroups of  $V$  to the normal subgroups of  $H$ ; we will show that it is an injection. Let  $t \in V$  be the image under  $i$  of some generator of  $\mathbb{Z}$  and consider two finite normal subgroups  $K_1$  and  $K_2$  of  $V$  with  $f(K_1) = f(K_2)$ . Consider  $k_1 \in K_1$ . We can find  $k_2 \in K_2$  and  $n \in \mathbb{Z}$  with  $k_2 = k_1 \cdot t^n$ . Then  $t^n$  belongs to the finite normal subgroup  $K_1 \cdot K_2$ . This implies  $n = 0$  and hence  $k_1 = k_2$ . This shows  $K_1 \subseteq K_2$ . By symmetry we get  $K_1 = K_2$ . Since  $H$  contains only finitely many subgroups, we conclude that there are only finitely many different finite normal subgroups in  $V$ . Now assertion (iii) follows.

(i) and (iv) Let  $V$  be an infinite virtually cyclic group. Then  $Q_V$  is an infinite virtually cyclic subgroup which does not contain a non-trivial finite normal subgroup.

There exists an exact sequence  $1 \rightarrow \mathbb{Z} \xrightarrow{i} Q_V \xrightarrow{f} H \rightarrow 1$  for some finite group  $H$ . There exists a subgroup of index at most two  $H' \subseteq H$  such that the conjugation action of  $H$  on  $\mathbb{Z}$  restricted to  $H'$  is trivial. Put  $Q'_V = f^{-1}(H')$ . Then the center of  $Q'_V$  contains  $i(\mathbb{Z})$  and hence is infinite. By assertion (ii) we can find an exact sequence  $1 \rightarrow K \rightarrow Q'_V \xrightarrow{f} \mathbb{Z} \rightarrow 1$  with finite  $K$ . The group  $Q'_V$  contains a unique maximal normal finite subgroup  $K'$  by assertion (iii). This implies that  $K' \subseteq Q'_V$  is characteristic. Since  $Q'_V$  is a normal subgroup of  $Q_V$ ,  $K' \subseteq Q_V$  is a normal subgroup and therefore  $K'$  is trivial. Hence  $Q'_V$  contains no non-trivial finite normal subgroup. This implies that  $Q'_V$  is infinite cyclic. Since  $Q'_V$  is a normal subgroup of index 2 in  $Q_V$  and  $Q_V$  contains no non-trivial finite normal subgroup,  $Q_V$  is infinite cyclic or  $D_\infty$ .

In particular we see that every infinite virtual cyclic group is of type I or of type II. It remains to show that an infinite virtually cyclic group  $V$  which is of type II cannot be of type I. If  $1 \rightarrow K \rightarrow V \rightarrow D_\infty \rightarrow 1$  is an extension with finite  $K$ , then we obtain from the Lyndon-Serre spectral sequence an exact sequence  $H_1(K) \otimes_{\mathbb{Z}Q} \mathbb{Z} \rightarrow H_1(V) \rightarrow H_1(D_\infty)$ . Hence  $H_1(V)$  is finite, since both  $H_1(D_\infty)$  and  $H_1(K)$  are finite. We conclude from assertion (ii) that  $V$  is not of type I. This finishes the proof of assertions (i) and (iv).

(v) Since  $V$  is virtually cyclic, the kernel of  $f$  is finite. Since  $Q$  does not contain a non-trivial finite normal subgroup, every normal finite subgroup of  $V$  is contained in the kernel of  $f$ . Hence  $\ker(f)$  is the unique maximal finite normal subgroup of  $V$ .

(vi) Since  $K_W$  is finite and the image of  $\phi$  is by assumption infinite, the composite  $p_W \circ \phi: V \rightarrow Q_W$  has infinite image. Since  $Q_W$  is isomorphic to  $\mathbb{Z}$  or  $D_\infty$ , the same is true for the image of  $p_W \circ \phi: V \rightarrow Q_W$ . By assertion (v) the kernel of  $p_W \circ \phi: V \rightarrow Q_W$  is  $K_V$ . Hence  $\phi(K_V) \subseteq K_W$  and  $\phi$  induces maps  $\phi_K$  and  $\phi_Q$

making the diagram appearing in assertion (vi) commutative. Since the image of  $p_W \circ \phi: V \rightarrow Q_W$  is infinite,  $\phi_Q(Q_V)$  is infinite. This implies that  $\phi_Q$  is injective since both  $Q_V$  and  $Q_W$  are isomorphic to  $D_\infty$  or  $\mathbb{Z}$ . This finishes the proof of Lemma 1.1.  $\square$

## 2. SOME CATEGORIES ATTACHED TO HOMOGENEOUS SPACES

Let  $G$  be a group and let  $S$  be a  $G$ -set, for instance a homogeneous space  $G/H$ . Let  $\mathcal{G}^G(S)$  be the associated *transport groupoid*. Objects are the elements in  $S$ . The set of morphisms from  $s_1$  to  $s_2$  consists of those elements  $g \in G$  for which  $gs_1 = s_2$ . Composition is given by the group multiplication in  $G$ . Obviously  $\mathcal{G}^G(S)$  is a connected groupoid if  $G$  acts transitively on  $S$ . A  $G$ -map  $f: S \rightarrow T$  induces a functor  $\mathcal{G}^G(f): \mathcal{G}^G(S) \rightarrow \mathcal{G}^G(T)$  by sending an object  $s \in S$  to  $f(s)$  and a morphism  $g: s_1 \rightarrow s_2$  to the morphism  $g: f(s_1) \rightarrow f(s_2)$ . We mention that for two objects  $s_1$  and  $s_2$  in  $\mathcal{G}^G(S)$  the induced map  $\text{mor}_{\mathcal{G}^G(S)}(s_1, s_2) \rightarrow \text{mor}_{\mathcal{G}^G(T)}(f(s_1), f(s_2))$  is injective.

A functor  $F: \mathcal{C}_0 \rightarrow \mathcal{C}_1$  of categories is called an *equivalence* if there exists a functor  $F': \mathcal{C}_1 \rightarrow \mathcal{C}_0$  with the property that  $F' \circ F$  is naturally equivalent to the identity functor  $\text{id}_{\mathcal{C}_0}$  and  $F \circ F'$  is naturally equivalent to the identity functor  $\text{id}_{\mathcal{C}_1}$ . A functor  $F$  is a natural equivalence if and only if it is *essentially surjective* (i.e., it induces a bijection on the isomorphism classes of objects) and it is *full* and *faithful*, (i.e., for any two objects  $c, d$  in  $\mathcal{C}_0$  the induced map  $\text{mor}_{\mathcal{C}_0}(c, d) \rightarrow \text{mor}_{\mathcal{C}_1}(F(c), F(d))$  is bijective).

Given a monoid  $M$ , let  $\widehat{M}$  be the category with precisely one object and  $M$  as the monoid of endomorphisms of this object. For any subgroup  $H$  of  $G$ , the inclusion

$$e(G/H): \widehat{H} \rightarrow \mathcal{G}^G(G/H), \quad g \mapsto (eH \xrightarrow{g} eH)$$

(where  $e \in G$  is the unit element) is an equivalence of categories, whose inverse sends  $g: g_1H \rightarrow g_2H$  to  $g_2^{-1}gg_1 \in G$ .

Now fix an infinite virtually cyclic subgroup  $V \subseteq G$  of type I. Then  $Q_V$  is an infinite cyclic group. Let  $\text{gen}(Q_V)$  be the set of generators. Given a generator  $\sigma \in \text{gen}(Q_V)$ , define  $Q_V[\sigma]$  to be the submonoid of  $Q_V$  consisting of elements of the form  $\sigma^n$  for  $n \in \mathbb{Z}, n \geq 0$ . Let  $V[\sigma] \subseteq V$  be the submonoid given by  $p_V^{-1}(Q_V[\sigma])$ . Let  $\mathcal{G}^G(G/V)[\sigma]$  be the subcategory of  $\mathcal{G}^G(G/V)$  whose objects are the objects in  $\mathcal{G}^G(G/V)$  and whose morphisms  $g: g_1V \rightarrow g_2V$  satisfy  $g_2^{-1}gg_1 \in V[\sigma]$ . Notice that  $\mathcal{G}^G(G/V)[\sigma]$  is not a groupoid anymore, but any two objects are isomorphic. Let  $\mathcal{G}^G(G/V)_K$  be the subcategory of  $\mathcal{G}^G(G/V)$  whose objects are the objects in  $\mathcal{G}^G(G/V)$  and whose morphisms  $g: g_1V \rightarrow g_2V$  satisfy  $g_2^{-1}gg_1 \in K_V$ . Obviously  $\mathcal{G}^G(G/V)_K$  is a connected groupoid and a subcategory of  $\mathcal{G}^G(G/V)[\sigma]$ .

We obtain the following commutative diagram of categories

$$(2.1) \quad \begin{array}{ccc} \mathcal{G}^G(G/V)[\sigma] & \xrightarrow{j_{(G/V)[\sigma]}} & \mathcal{G}^G(G/V) \\ \uparrow \simeq e(G/V)[\sigma] & & \simeq \uparrow e(G/V) \\ \widehat{V[\sigma]} & \xrightarrow{\widehat{j_V[\sigma]}} & \widehat{V} \end{array}$$

whose horizontal arrows are induced by the obvious inclusions and whose left vertical arrow is the restriction of  $e(G/V)$  (and is also an equivalence of categories). The functor  $e(G/V)$  also restricts to an equivalence of categories

$$(2.2) \quad e(G/V)_K: \widehat{K_V} \xrightarrow{\simeq} \mathcal{G}^G(G/V)_K.$$

*Remark.* The relation of the categories  $\widehat{K_V}$ ,  $\widehat{V[\sigma]}$  and  $\widehat{V}$  to  $\mathcal{G}^G(G/V)_K$ ,  $\mathcal{G}^G(G/V)[\sigma]$  and  $\mathcal{G}^G(G/V)$  is analogous to the relation of the fundamental group of a path connected space to its fundamental groupoid.

Let  $\bar{\sigma} \in V$  be any element which is mapped under the projection  $p_V: V \rightarrow Q_V$  to the fixed generator  $\sigma$ . Right multiplication with  $\bar{\sigma}$  induces a  $G$ -map  $R_\sigma: G/K_V \rightarrow G/K_V$ ,  $gK_V \mapsto g\bar{\sigma}K_V$ . One easily checks that  $R_\sigma$  depends only on  $\sigma$  and is independent of the choice of  $\bar{\sigma}$ . Let  $\text{pr}_V: G/K_V \rightarrow G/V$  be the projection. We obtain the following commutative diagram

$$(2.3) \quad \begin{array}{ccc} \mathcal{G}^G(G/K_V) & \xrightarrow{R_\sigma} & \mathcal{G}^G(G/K_V) \\ & \searrow \mathcal{G}^G(\text{pr}_V) & \swarrow \mathcal{G}^G(\text{pr}_V) \\ & & \mathcal{G}^G(G/V) \end{array}$$

### 3. HOMOTOPY COLIMITS OF $\mathbb{Z}$ -LINEAR AND ADDITIVE CATEGORIES

Homotopy colimits of additive categories have been defined for instance in [1, Section 5]. Here we review its definition and describe some properties, first in the setting of  $\mathbb{Z}$ -linear categories.

Recall that a  $\mathbb{Z}$ -linear category is a category where all Hom-sets are provided with the structure of abelian groups, such that composition is bilinear. Denote by  $\mathbb{Z}\text{-Cat}$  the category whose objects are  $\mathbb{Z}$ -linear categories and whose morphisms are additive functors between them. Given a collection of  $\mathbb{Z}$ -linear categories  $(\mathcal{A}_i)_{i \in I}$ , their coproduct  $\coprod_{i \in I} \mathcal{C}_i$  in  $\mathbb{Z}\text{-Cat}$  exists and has the following explicit description: Objects are pairs  $(i, X)$  where  $i \in I$  and  $X \in \mathcal{A}_i$ . The abelian group of morphisms  $(i, X) \rightarrow (j, Y)$  is non-zero only if  $i = j$  in which case it is  $\text{mor}_{\mathcal{A}_i}(X, Y)$ .

Let  $\mathcal{C}$  be a small category. Given a contravariant functor  $F: \mathcal{C} \rightarrow \mathbb{Z}\text{-Cat}$ , its *homotopy colimit* (see for instance [24]).

$$(3.1) \quad \int_{\mathcal{C}} F$$

is the  $\mathbb{Z}$ -linear category obtained from the coproduct  $\coprod_{c \in \mathcal{C}} F(c)$  by adjoining morphisms

$$T_f: (d, f^*X) \rightarrow (c, X)$$

for each  $(c, X) \in \coprod_{c \in \mathcal{C}} F(c)$  and each morphism  $f: d \rightarrow c$  in  $\mathcal{C}$ . (Here we write  $f^*X$  for  $F(f)(X)$ .) They are subject to the relations that  $T_{\text{id}} = \text{id}$  and that all possible diagrams

$$\begin{array}{ccc} (e, g^*f^*X) & \xrightarrow{T_g} & (d, f^*X) \\ & \searrow T_{f \circ g} & \downarrow T_f \\ & & (c, X) \end{array} \quad \begin{array}{ccc} (d, f^*X) & \xrightarrow{T_f} & (c, X) \\ \downarrow f^*u & & \downarrow u \\ (d, f^*Y) & \xrightarrow{T_f} & (c, Y) \end{array}$$

are to be commutative.

Hence, a morphism in  $\int_{\mathcal{C}} F$  from  $(x, A)$  to  $(y, B)$  can be uniquely written as a sum

$$(3.2) \quad \sum_{f \in \text{mor}_{\mathcal{C}}(x, y)} T_f \circ \phi_f$$

where  $\phi_f: A \rightarrow f^*B$  is a morphism in  $F(x)$  and all but finitely many of the morphisms  $\phi_f$  are zero. The composition of two such morphisms can be determined by the distributivity law and the rule

$$(T_f \circ \phi) \circ (T_g \circ \psi) = T_{f \circ g} \circ (g^*\phi \circ \psi)$$

which just follows the fact that both upper squares are commutative.

Using this description, it follows that the homotopy colimit has the following universal property for additive functors  $\int_{\mathcal{C}} F \rightarrow \mathcal{A}$  into some other  $\mathbb{Z}$ -linear category  $\mathcal{A}$ :

Suppose that we are given additive functors  $j_c: F(c) \rightarrow \mathcal{A}$ , for each  $c \in \mathcal{C}$ , and morphisms  $S_f: j_d(f^*X) \rightarrow j_c(X)$  for each  $X \in F(c)$  and each  $f: d \rightarrow c$  in  $\mathcal{C}$ . If  $S_{\text{id}} = \text{id}$  and all possible diagrams

$$\begin{array}{ccc} j_c(g^*f^*X) & \xrightarrow{S_g} & j_d(f^*X) \\ & \searrow S_{f \circ g} & \downarrow S_f \\ & & j_c(X) \end{array} \qquad \begin{array}{ccc} j_d(f^*X) & \xrightarrow{S_f} & j_c(X) \\ \downarrow j_d(f^*u) & & \downarrow j_c(u) \\ j_d(f^*Y) & \xrightarrow{S_f} & j_c(Y) \end{array}$$

are commutative, then this data specifies an additive functor  $\int_{\mathcal{C}} F \rightarrow \mathcal{A}$  by sending  $T_f$  to  $S_f$ .

The homotopy colimit is functorial in  $F$ . Namely, if  $S: F_0 \rightarrow F_1$  is a natural transformation of contravariant functors  $\mathcal{C} \rightarrow \mathbb{Z}\text{-Cat}$ , then it induces an additive functor

$$(3.3) \quad \int_{\mathcal{C}} S: \int_{\mathcal{C}} F_0 \rightarrow \int_{\mathcal{C}} F_1$$

of  $\mathbb{Z}$ -linear categories. It is defined using the universal property by sending  $F_0(c)$  to  $F_1(c) \subset \int_{\mathcal{C}} F_1$  via  $S$  and “sending  $T_f$  to  $T_f$ ”. In more detail, the image of  $T_f: (c, f^*(X)) \rightarrow (d, X)$  (in  $\int_{\mathcal{C}} F_0$ ) is given by  $T_f: (c, f^*(S(X))) \rightarrow (d, S(X))$  (in  $\int_{\mathcal{C}} F_1$ ). Obviously we have for  $S_1: F_0 \rightarrow F_1$  and  $S_2: F_1 \rightarrow F_2$

$$(3.4) \quad \left( \int_{\mathcal{C}} S_2 \right) \circ \left( \int_{\mathcal{C}} S_1 \right) = \int_{\mathcal{C}} (S_2 \circ S_1);$$

$$(3.5) \quad \int_{\mathcal{C}} \text{id}_F = \text{id}_{\int_{\mathcal{C}} F}.$$

The construction is also functorial in  $\mathcal{C}$ . Namely, let  $W: \mathcal{C}_1 \rightarrow \mathcal{C}_2$  be a covariant functor. Then we obtain a covariant functor

$$(3.6) \quad W_*: \int_{\mathcal{C}_1} F \circ W \rightarrow \int_{\mathcal{C}_2} F$$

of additive categories which is the identity on each  $F(W(c))$  and sends “ $T_f$  to  $T_{W(f)}$ ”, again interpreted appropriately. For covariant functors  $W_1: \mathcal{C}_1 \rightarrow \mathcal{C}_2$ ,  $W_2: \mathcal{C}_2 \rightarrow \mathcal{C}_3$  and a contravariant functor  $F: \mathcal{C}_3 \rightarrow \text{Add-Cat}$  we have

$$(3.7) \quad (W_2)_* \circ (W_1)_* = (W_2 \circ W_1)_*;$$

$$(3.8) \quad (\text{id}_{\mathcal{C}})_* = \text{id}_{\int_{\mathcal{C}} F}.$$

These two constructions are compatible. Namely, given a natural transformation  $S: F_1 \rightarrow F_2$  of contravariant functors  $\mathcal{C}_2 \rightarrow \mathbb{Z}\text{-Cat}$  and a covariant functor  $W: \mathcal{C}_1 \rightarrow \mathcal{C}_2$ , we get

$$(3.9) \quad \left( \int_{\mathcal{C}_2} S \right) \circ W_* = W_* \circ \left( \int_{\mathcal{C}_1} (S \circ W) \right).$$

**Lemma 3.10.** (i) *Let  $W: \mathcal{D} \rightarrow \mathcal{C}$  be an equivalence of categories. Let  $F: \mathcal{C} \rightarrow \mathbb{Z}\text{-Cat}$  be a contravariant functor. Then*

$$W_*: \int_{\mathcal{D}} F \circ W \rightarrow \int_{\mathcal{C}} F$$

*is an equivalence of categories;*

(ii) Let  $\mathcal{C}$  be a category and let  $S: F_1 \rightarrow F_2$  be a transformation of contravariant functors  $\mathcal{C} \rightarrow \mathbb{Z}\text{-Cat}$  such that for every object  $c$  in  $\mathcal{C}$  the functor  $S(c): F_0(c) \rightarrow F_1(c)$  is an equivalence of categories. Then

$$\int_{\mathcal{C}} S: \int_{\mathcal{C}} F_1 \rightarrow \int_{\mathcal{C}} F_2$$

is an equivalence of categories.

The proof is an easy exercise. Note the general fact that if  $F: \mathcal{C} \rightarrow \mathcal{D}$  is an additive functor between  $\mathbb{Z}$ -linear categories such that  $F$  is an equivalence between the underlying categories, then it follows automatically that there exists an additive inverse equivalence  $F'$  and two additive natural equivalences  $F' \circ F \simeq \text{id}_{\mathcal{C}}$  and  $F \circ F' \simeq \text{id}_{\mathcal{D}}$ .

**Notation 3.11.** If  $W: \mathcal{C}_1 \rightarrow \mathcal{C}$  is the inclusion of a subcategory, then the same is true for  $W_*$ . If no confusion is possible, we just write

$$\int_{\mathcal{C}_1} F := \int_{\mathcal{C}_1} F \circ W \subset \int_{\mathcal{C}} F.$$

Denote by  $\text{Add-Cat}$  the category whose objects are additive categories and whose morphisms are given by additive functors between them. Notice that  $\int_{\mathcal{C}} F$  is not necessarily an additive category even if all the  $F(c)$  are – the direct sum  $(c, X) \oplus (d, Y)$  need not exist. However any isomorphism  $f: c \rightarrow d$  in  $\mathcal{C}$  induces an isomorphism  $T_f: (c, f^*Y) \rightarrow (d, Y)$  so that

$$(c, X) \oplus (d, Y) \cong (c, X) \oplus (c, f^*Y) \cong (c, X \oplus f^*Y).$$

Hence, if in the index category all objects are isomorphic and all the  $F(c)$  are additive, then  $\int_{\mathcal{C}} F$  is an additive category. As for additive categories  $\mathcal{A}, \mathcal{B}$  we have

$$\text{mor}_{\mathbb{Z}\text{-Cat}}(\mathcal{A}, \mathcal{B}) = \text{mor}_{\text{Add-Cat}}(\mathcal{A}, \mathcal{B})$$

(in both cases the morphisms are just additive functors), the universal property for additive functors  $\int_{\mathcal{C}} F \rightarrow \mathcal{A}$  into  $\mathbb{Z}$ -linear categories extends to a universal property for additive functors into additive categories.

In the general case of an arbitrary indexing category, the homotopy colimit in the setting of additive categories still exists. It is obtained by freely adjoining direct sums to the homotopy colimit for  $\mathbb{Z}$ -linear categories; the universal properties then holds in the setting of “additive categories with choice of direct sum”. We will not discuss this in detail here since in all the cases we will consider, the indexing category has the property that any two objects are isomorphic.

**Notation 3.12.** If the indexing category  $\mathcal{C}$  has a single object and  $F: \mathcal{C} \rightarrow \mathbb{Z}\text{-Cat}$  is a contravariant functor, then we will write  $X$  instead of  $(*, X)$  for a typical element of the homotopy colimit. The structural morphisms in  $\int_{\mathcal{C}} F$  thus take the simple form

$$T_f: f^*X \rightarrow X$$

for  $f$  a morphism (from the single object to itself) in  $\mathcal{C}$ .

#### 4. THE TWISTED BASS-HELLER-SWAN THEOREM FOR ADDITIVE CATEGORIES

Given an additive category  $\mathcal{A}$ , we denote by  $\mathbf{K}(\mathcal{A})$  the non-connective  $K$ -theory spectrum associated to it (after idempotent completion), see [20], [22]. Thus we obtain a covariant functor

$$(4.1) \quad \mathbf{K}: \text{Add-Cat} \rightarrow \text{Spectra}.$$

Let  $\mathcal{B}$  be an additive  $\mathbb{Z}$ -category, i.e. an additive category with a right action of the infinite cyclic group. Fix a generator  $\sigma$  of the infinite cyclic group  $\mathbb{Z}$ . Let

$\Phi: \mathcal{B} \rightarrow \mathcal{B}$  be the automorphism of additive categories given by multiplication with  $\sigma$ . Of course one can recover the  $\mathbb{Z}$ -action from  $\Phi$ . Since  $\widehat{\mathbb{Z}}$  has precisely one object, we can and will identify the set of objects of  $\int_{\widehat{\mathbb{Z}}} \mathcal{B}$  and  $\mathcal{B}$  in the sequel. Let  $i_{\mathcal{B}}: \mathcal{B} \rightarrow \int_{\widehat{\mathbb{Z}}} \mathcal{B}$  be the inclusion into the homotopy colimit.

The structural morphisms  $T_{\sigma}: \Phi(B) \rightarrow B$  of  $\int_{\widehat{\mathbb{Z}}} \mathcal{B}$  assemble to a natural isomorphism  $i_{\mathcal{B}} \circ \Phi \rightarrow i_{\mathcal{B}}$  in the following diagram:

$$\begin{array}{ccc} \mathcal{B} & \xrightarrow{\Phi} & \mathcal{B} \\ & \searrow i_{\mathcal{B}} & \swarrow i_{\mathcal{B}} \\ & \int_{\widehat{\mathbb{Z}}} \mathcal{B} & \end{array}$$

If we apply the non-connective  $K$ -theory spectrum to it, we obtain a diagram of spectra which commutes up to preferred homotopy.

$$\begin{array}{ccc} \mathbf{K}(\mathcal{B}) & \xrightarrow{\mathbf{K}(\Phi)} & \mathbf{K}(\mathcal{B}) \\ & \searrow \mathbf{K}(i_{\mathcal{B}}) & \swarrow \mathbf{K}(i_{\mathcal{B}}) \\ & \mathbf{K}\left(\int_{\widehat{\mathbb{Z}}} \mathcal{B}\right) & \end{array}$$

It induces a map of spectra

$$\mathbf{a}_{\mathcal{B}}: T_{\mathbf{K}(\Phi)} \rightarrow \mathbf{K}\left(\int_{\widehat{\mathbb{Z}}} \mathcal{B}\right)$$

where  $T_{\mathbf{K}(\Phi)}$  is the mapping torus of the map of spectra  $\mathbf{K}(\Phi): \mathbf{K}(\mathcal{B}) \rightarrow \mathbf{K}(\mathcal{B})$  which is defined as the pushout

$$\begin{array}{ccc} \mathbf{K}(\mathcal{B}) \wedge \{0, 1\}_+ = \mathbf{K}(\mathcal{B}) \vee \mathbf{K}(\mathcal{B}) & \xrightarrow{\mathbf{K}(\Phi) \vee \text{id}_{\mathbf{K}(\mathcal{B})}} & \mathbf{K}(\mathcal{B}) \\ \downarrow & & \downarrow \\ \mathbf{K}(\mathcal{B}) \wedge [0, 1]_+ & \longrightarrow & T_{\mathbf{K}(\Phi)} \end{array}$$

Denote by  $\mathbb{Z}[\sigma]$  the submonoid  $\{\sigma^n \mid n \in \mathbb{Z}, n \geq 0\}$  generated by  $\sigma$ . Let  $j[\sigma]: \mathbb{Z}[\sigma] \rightarrow \mathbb{Z}$  be the inclusion. Let  $i_{\mathcal{B}}[\sigma]: \mathcal{B} \rightarrow \int_{\widehat{\mathbb{Z}[\sigma]}} \mathcal{B}$  be the inclusion induced by  $i_{\mathcal{B}}$ . Define a functor of additive categories

$$\text{ev}_{\mathcal{B}}[\sigma]: \int_{\widehat{\mathbb{Z}[\sigma]}} \mathcal{B} \rightarrow \mathcal{B}$$

extending the identity on  $\mathcal{B}$  by sending a morphism  $T_{\sigma^n}$  to 0 for  $n > 0$ . (Of course  $\sigma^0 = \text{id}$  must go to the identity.) We obtain the following diagram of spectra

$$\begin{array}{ccccc} \mathbf{K}(\mathcal{B}) & \xrightarrow{\mathbf{K}(i_{\mathcal{B}}[\sigma])} & \mathbf{K}\left(\int_{\widehat{\mathbb{Z}[\sigma]}} \mathcal{B}\right) & \xrightarrow{\mathbf{K}(\text{ev}_{\mathcal{B}}[\sigma])} & \mathbf{K}(\mathcal{B}) \\ & \searrow & & \swarrow & \\ & & \text{id} & & \end{array}$$

Define  $\mathbf{NK}(\mathcal{B}, \sigma)$  as the homotopy fiber of the map  $\mathbf{K}(\text{ev}_{\mathcal{B}}[\sigma]): \mathbf{K}\left(\int_{\widehat{\mathbb{Z}[\sigma]}} \mathcal{B}\right) \rightarrow \mathbf{K}(\mathcal{B})$ . Let  $\mathbf{b}_{\mathcal{B}}[\sigma]$  denote the composite

$$\mathbf{b}_{\mathcal{B}}[\sigma]: \mathbf{NK}(\mathcal{B}, \sigma) \rightarrow \mathbf{K}\left(\int_{\widehat{\mathbb{Z}[\sigma]}} \mathcal{B}\right) \rightarrow \mathbf{K}\left(\int_{\widehat{\mathbb{Z}}} \mathcal{B}\right)$$

of the canonical map with the inclusion. Let  $\text{gen}(\mathbb{Z})$  be the set of generators of the infinite cyclic group  $\mathbb{Z}$ . Put

$$\mathbf{NK}(\mathcal{B}) := \bigvee_{\sigma \in \text{gen}(\mathbb{Z})} \mathbf{NK}(\mathcal{B}, \sigma)$$

and define

$$\mathbf{b}_{\mathcal{B}} := \bigvee_{\sigma \in \text{gen}(\mathbb{Z})} \mathbf{b}_{\mathcal{B}}[\sigma]: \bigvee_{\sigma \in \text{gen}(\mathbb{Z})} \mathbf{NK}(\mathcal{B}, \sigma) \rightarrow \mathbf{K} \left( \int_{\widehat{\mathbb{Z}}} \mathcal{B} \right).$$

The proof of the following result can be found in [19]. The case where the  $\mathbb{Z}$ -action on  $\mathcal{B}$  is trivial and one considers only  $K$ -groups in dimensions  $n \leq 1$  has already been treated by Ranicki [23, Chapter 10 and 11]. If  $R$  is a ring with an automorphism and one takes  $\mathcal{B}$  to be the category  $R$ -FGF of finitely generated free  $R$ -modules with the induced  $\mathbb{Z}$ -action, Theorem 4.2 boils down for higher algebraic  $K$ -theory to the twisted Bass-Heller-Swan-decomposition of Grayson [11, Theorem 2.1 and Theorem 2.3]).

**Theorem 4.2** (Twisted Bass-Heller-Swan decomposition for additive categories).  
*The map of spectra*

$$\mathbf{a}_{\mathcal{B}} \vee \mathbf{b}_{\mathcal{B}}: T_{\mathbf{K}(\Phi)} \vee \mathbf{NK}(\mathcal{B}) \xrightarrow{\cong} \mathbf{K} \left( \int_{\widehat{\mathbb{Z}}} \mathcal{B} \right)$$

*is a weak equivalence of spectra.*

## 5. SOME ADDITIVE CATEGORIES ASSOCIATED TO AN ADDITIVE $G$ -CATEGORY

Let  $G$  be a group. Let  $\mathcal{A}$  be an additive  $G$ -category, i.e., an additive category with a right  $G$ -operation by isomorphisms of additive categories. We can consider  $\mathcal{A}$  as a contravariant functor  $\widehat{G} \rightarrow \text{Add-Cat}$ . Fix a homogeneous  $G$ -space  $G/H$ . Let  $\text{pr}_{G/H}: \mathcal{G}^G(G/H) \rightarrow \mathcal{G}^G(G/G) = \widehat{G}$  be the projection induced by the canonical  $G$ -map  $G/H \rightarrow G/G$ . Then we obtain a covariant functor  $\mathcal{G}^G(G/H) \rightarrow \text{Add-Cat}$  by sending  $G/H$  to  $\mathcal{A} \circ \text{pr}_G$ . Let  $\int_{\mathcal{G}^G(G/H)} \mathcal{A} \circ \text{pr}_{G/H}$  be the additive category given by the homotopy colimit (defined in (3.1)) of this functor. A  $G$ -map  $f: G/H \rightarrow G/K$  induces a functor  $\mathcal{G}^G(f): \mathcal{G}^G(G/H) \rightarrow \mathcal{G}^G(G/K)$  which is compatible with the projections to  $\widehat{G}$ . Hence it induces a functor of additive categories, see (3.6)

$$\mathcal{G}^G(f)_*: \int_{\mathcal{G}^G(G/H)} \mathcal{A} \circ \text{pr}_{G/H} \rightarrow \int_{\mathcal{G}^G(G/K)} \mathcal{A} \circ \text{pr}_{G/K}.$$

Thus we obtain a covariant functor

$$(5.1) \quad \text{Or}(G) \rightarrow \text{Add-Cat}, \quad G/H \mapsto \int_{\mathcal{G}^G(G/H)} \mathcal{A} \circ \text{pr}_{G/H}.$$

**Remark 5.2.** Applying Lemma 3.10 (i) to the equivalence of categories  $e(G/H): \widehat{H} \rightarrow \mathcal{G}^G(G/H)$ , we see that the functor (5.1), at  $G/H$ , takes the value  $\int_{\widehat{H}} \mathcal{A}$  where  $\mathcal{A}$  carries the restricted  $H$ -action. The more complicated description is however needed for the functoriality.

**Notation 5.3.** For the sake of brevity, we will just write  $\mathcal{A}$  for any composite  $\mathcal{A} \circ \text{pr}_{G/H}$  if no confusion is possible. In this notation, (5.1) takes the form

$$G/H \mapsto \int_{\mathcal{G}^G(G/H)} \mathcal{A}.$$

Let  $V \subseteq G$  be an infinite virtually cyclic subgroup of type I. In the sequel we abbreviate  $K = K_V$  and  $Q = Q_V$ . Let  $\text{pr}_K: \mathcal{G}^G(G/V)_K \rightarrow \widehat{K}$  the functor which sends a morphism  $g: g_1V \rightarrow g_2V$  to  $g_2^{-1}gg_1 \in K$ .

Fixing a generator  $\sigma$  of the infinite cyclic group  $Q$ , the inclusions  $\mathcal{G}^G(G/V)_K \subset \mathcal{G}^G(G/V)[\sigma] \subset \mathcal{G}^G(G/V)$  induce inclusions

$$(5.4) \quad \int_{\mathcal{G}^G(G/V)_K} \mathcal{A} \subset \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} \subset \int_{\mathcal{G}^G(G/V)} \mathcal{A}.$$

Actually the category into the middle retracts onto the the smaller one. To see this, define a retraction

$$(5.5) \quad \text{ev}(G/V)[\sigma]_K: \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} \rightarrow \int_{\mathcal{G}^G(G/V)_K} \mathcal{A}$$

as follows. It is the identity on every copy of the additive category  $\mathcal{A}$  inside the homotopy colimit. Let  $T_g: (g_1V, g^*A) \rightarrow (g_2V, A)$  be a structural morphism in the homotopy colimit, where  $g: g_1V \rightarrow g_2V$  in  $\mathcal{G}^G(G/V)[\sigma]$  is a morphism in  $\mathcal{G}^G(G/V)[\sigma]$  (that is,  $g$  is an element of  $G$  satisfying  $g_2^{-1}gg_1 \in V[\sigma]$ ). If

$$g_2^{-1}gg_1 \in K \subset V[\sigma],$$

then  $g$  is by definition a morphism in  $\mathcal{G}^G(G/V)_K \subset \mathcal{G}^G(G/V)[\sigma]$  and we may let

$$\text{ev}(G/V)[\sigma]_K(T_g) = T_g.$$

Otherwise we send the morphism  $T_g$  to 0. This is well-defined, since for two elements  $h_1, h_2 \in V[\sigma]$  we have  $h_1h_2 \in K$  if and only if both  $h_1 \in K$  and  $h_2 \in K$  hold.

Similarly the inclusion  $\int_{\widehat{K}} \mathcal{A} \subset \int_{\widehat{V[\sigma]}} \mathcal{A}$  is split by a retraction

$$\text{ev}_V[\sigma]: \int_{\widehat{V[\sigma]}} \mathcal{A} \rightarrow \int_{\widehat{K}} \mathcal{A}$$

defined as follows: On the copy of  $\mathcal{A}$  inside  $\int_{\widehat{V[\sigma]}} \mathcal{A}$ , the functor is defined to be the identity. A structural morphism  $T_g: g^*A \rightarrow A$  is sent to itself if  $g \in K$ , and to zero otherwise. One easily checks that the following diagram commutes (where the unlabelled arrows are inclusions) and has equivalences of additive categories as vertical maps.

$$(5.6) \quad \begin{array}{ccccc} & & \text{id} & & \\ & & \curvearrowright & & \\ \int_{\mathcal{G}^G(G/V)_K} \mathcal{A} & \longrightarrow & \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} & \xrightarrow{\text{ev}(G/V)[\sigma]} & \int_{\mathcal{G}^G(G/V)_K} \mathcal{A} \\ \uparrow \simeq (e(G/V)_K)_* & & \uparrow \simeq e(G/V)[\sigma]_* & & \uparrow \simeq (e(G/V)_K)_* \\ \int_{\widehat{K}} \mathcal{A} & \longrightarrow & \int_{\widehat{V[\sigma]}} \mathcal{A} & \xrightarrow{\text{ev}_V[\sigma]} & \int_{\widehat{K}} \mathcal{A} \\ & & \text{id} & & \\ & & \curvearrowleft & & \end{array}$$

We obtain from (2.1) and Lemma 3.10 (i) the following commutative diagram of additive categories with equivalences of additive categories as vertical maps

$$(5.7) \quad \begin{array}{ccc} \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} & \longrightarrow & \int_{\mathcal{G}^G(G/V)} \mathcal{A} \\ \uparrow \simeq e(G/V)[\sigma]_* & & \simeq \uparrow e(G/V)_* \\ \int_{\widehat{V[\sigma]}} \mathcal{A} & \longrightarrow & \int_{\widehat{V}} \mathcal{A} \end{array}$$

(where again the unlabelled arrows are the inclusions).

Now we abbreviate  $\mathcal{B} = \int_{\widehat{K}} \mathcal{A}$ . Next we define a right  $Q$ -action on  $\mathcal{B}$  which will depend on a choice of an element  $\bar{\sigma} \in V$  such that  $p_V: V \rightarrow Q$  sends  $\bar{\sigma}$  to  $\sigma$ . Such an element induces a section of the projection  $G \rightarrow Q$  by which any action of  $G$  induces an action of  $Q$ . In short, the action of  $Q$  on  $\mathcal{B}$  is given by the action of  $G$  onto  $\mathcal{A} \subset \mathcal{B}$ , and by the conjugation action of  $Q$  on the indexing category  $\widehat{K}$ . In more detail, the action of  $\sigma \in Q$  is specified by the automorphism

$$\Phi: \int_{\widehat{K}} \mathcal{A} \rightarrow \int_{\widehat{K}} \mathcal{A}$$

defined as follows: A morphism  $\varphi: A \rightarrow B$  in  $\mathcal{A}$  is sent to  $\bar{\sigma}^* \varphi: \bar{\sigma}^* A \rightarrow \bar{\sigma}^* B$ , and a structural morphism  $T_g: g^* A \rightarrow A$  is sent to the morphism

$$T_{\bar{\sigma}^{-1}g\bar{\sigma}}: \bar{\sigma}^* g^* A = (\bar{\sigma}^{-1}g\bar{\sigma})^* \bar{\sigma}^* A \rightarrow \bar{\sigma}^* A.$$

With this notation we obtain an additive functor

$$\Psi: \int_{\widehat{Q}} \mathcal{B} \rightarrow \int_{\widehat{V}} \mathcal{A}$$

defined to extend the inclusion  $\mathcal{B} = \int_{\widehat{K}} \mathcal{A} \rightarrow \int_{\widehat{V}} \mathcal{A}$  and such that a structural morphism  $T_\sigma: \Phi(A) \rightarrow A$  is sent to  $T_{\bar{\sigma}}: \Phi(A) = \bar{\sigma}^* A \rightarrow A$ .

In more detail, a morphism in  $\int_{\widehat{Q}} \mathcal{B}$  can be uniquely written as a finite sum

$$\sum_{n \in \mathbb{Z}} T_{\bar{\sigma}^n} \circ \left( \sum_{k \in K} T_k \circ \phi_{k,n} \right) = \sum_{n,k} T_{\bar{\sigma}^n \cdot k} \circ \phi_{k,n}.$$

Since any element in  $V$  is uniquely a product  $\bar{\sigma}^n \cdot k$  with  $k \in K$ , the functor  $\Psi$  is fully faithful. As it is the identity on objects,  $\Psi$  is an isomorphism of categories. It also restricts to an isomorphism of categories

$$\Psi[\sigma]: \int_{\widehat{Q[\sigma]}} \mathcal{B} \rightarrow \int_{\widehat{V[\sigma]}} \mathcal{A}.$$

Define a functor

$$\text{ev}_{\mathcal{B}}[\sigma]: \int_{\widehat{Q[\sigma]}} \mathcal{B} \rightarrow \mathcal{B}$$

as follows. It is the identity functor on  $\mathcal{B}$ , and a non-identity structural morphism  $T_q: q^* \mathcal{B} \rightarrow \mathcal{B}$  is sent to 0. One easily checks using (5.6) and (5.7) that the following diagram of additive categories commutes (with unlabelled arrows given by inclusions) and that all vertical arrows are equivalences of additive categories:

$$(5.8) \quad \begin{array}{ccccc} \int_{G^G(G/V)_K} \mathcal{A} & \xleftarrow{\text{ev}(G/V)[\sigma]_K} & \int_{G^G(G/V)[\sigma]} \mathcal{A} & \xrightarrow{\quad} & \int_{G^G(G/V)} \mathcal{A} \\ \uparrow \simeq & & \uparrow \simeq & & \uparrow \simeq \\ (e(G/V)_K)_* & & e(G/V)[\sigma]_* & & e(G/V)_* \\ \int_{\widehat{K}} \mathcal{A} & \xleftarrow{\text{ev}_V[\sigma]} & \int_{\widehat{V[\sigma]}} \mathcal{A} & \xrightarrow{\quad} & \int_{\widehat{V}} \mathcal{A} \\ \uparrow \cong & & \uparrow \cong & & \uparrow \cong \\ \text{id} & & \Psi[\sigma] & & \Psi \\ \mathcal{B} & \xleftarrow{\text{ev}_{\mathcal{B}}[\sigma]} & \int_{\widehat{Q[\sigma]}} \mathcal{B} & \xrightarrow{\quad} & \int_{\widehat{Q}} \mathcal{B} \end{array}$$

Recall from section 2 that  $q_V: G/K \rightarrow G/V$  is the projection and that  $R_\sigma$  is the automorphism of  $\int_{G^G(G/K)} \mathcal{A}$  induced by right multiplication with  $\bar{\sigma}$ .

We have the following (not necessarily commutative) diagram of additive categories all of whose vertical arrows are equivalences of additive categories and the

unlabelled arrows are the inclusions.

$$(5.9) \quad \begin{array}{ccccc} \int_{\mathcal{G}^G(G/K)} \mathcal{A} & \xrightarrow{R_\sigma} & \int_{\mathcal{G}^G(G/K)} \mathcal{A} & & \\ \uparrow \scriptstyle (e(G/V)_K)_* \simeq & \searrow \scriptstyle \mathcal{G}^G(\text{pr}_V)_* & \int_{\mathcal{G}^G(G/V)} \mathcal{A} & \swarrow \scriptstyle \mathcal{G}^G(\text{pr}_V)_* & \uparrow \scriptstyle (e(G/V)_K)_* \simeq \\ \int_{\widehat{K}} \mathcal{A} & \xrightarrow{\quad} & \int_{\widehat{V}} \mathcal{A} & \xrightarrow{\Phi} & \int_{\widehat{K}} \mathcal{A} \\ \uparrow \scriptstyle \text{id} \simeq & \searrow & \uparrow \scriptstyle e(G/V)_* \simeq & & \swarrow \scriptstyle \text{id} \simeq \\ \mathcal{B} & \xrightarrow{\quad} & \int_{\widehat{V}} \mathcal{A} & \xrightarrow{\Phi} & \mathcal{B} \\ & \searrow \scriptstyle i_{\mathcal{B}} & \uparrow \scriptstyle \Psi \simeq & \swarrow \scriptstyle i_{\mathcal{B}} & \\ & & \int_{\widehat{Q}} \mathcal{B} & & \end{array}$$

The lowest triangle commutes up to a preferred natural isomorphism  $T: i_{\mathcal{B}} \circ \Phi \xrightarrow{\cong} i_{\mathcal{B}}$  which is part of the structural data of the homotopy colimit. We equip the middle triangle with the natural isomorphism  $\Psi \circ T$ . Explicitly it is just given by the structural morphisms  $T_{\bar{\sigma}}: \bar{\sigma}^* A \rightarrow A$ .

The three squares ranging from the middle to the lower level commute and the two natural equivalences above are compatible with these squares. The top triangle commutes. The back upper square commutes up to a preferred natural isomorphism  $S: (e(G/V)_K)_* \circ \Phi \xrightarrow{\cong} R_\sigma \circ (e(G/V)_K)_*$ . It assigns to an object  $A \in \mathcal{A}$ , which is the same as an object in  $\int_{\widehat{K}} \mathcal{A}$ , the structural isomorphism

$$S(A) := T_{\bar{\sigma}}: (eK, \bar{\sigma}^* A) \rightarrow (\bar{\sigma}K, A).$$

The other two squares joining the upper to the middle level commute. From the explicit description of the natural isomorphisms it becomes apparent that the preferred natural isomorphism for the middle triangle defined above and the preferred natural isomorphism for the upper back square are compatible in the sense that  $e(G/V)[\sigma]_* \circ \Psi \circ T = \mathcal{G}^G(\text{pr}_V)_* \circ S$ .

## 6. SOME $K$ -THEORY-SPECTRA OVER THE ORBIT CATEGORY

In this section we introduce various  $K$ -theory spectra. For a detailed introduction to spaces, spectra and modules over a category and some constructions of  $K$ -theory spectra, we refer to [5].

Given an additive  $G$ -category  $\mathcal{A}$ , we obtain a covariant  $\text{Or}(G)$ -spectrum

$$(6.1) \quad \mathbf{K}_{\mathcal{A}}^G: \text{Or}(G) \rightarrow \text{Spectra}, \quad G/H \mapsto \mathbf{K} \left( \int_{\mathcal{G}^G(G/H)} \mathcal{A} \circ \text{pr}_{G/H} \right).$$

by the composite of the two functors (4.1) and (5.1). It is naturally equivalent to the covariant  $\text{Or}(G)$ -spectrum which is denoted in the same way and constructed in [2, Definition 3.1].

We again adopt notation 5.3, abbreviating an expression such as  $\mathcal{A} \circ \text{pr}_{G/H}$  just by  $\mathcal{A}$ . Given a virtually cyclic subgroup  $V \subseteq G$ , we obtain the following map of

spectra induced by the functors  $j(G/V)[\sigma]_*$  of (5.4) and  $\text{ev}(G/V)[\sigma]$  of (5.5)

$$\mathbf{K} \left( \int_{\mathcal{G}^G(G/V)_K} \mathcal{A} \right) \xleftarrow{\mathbf{K}(\text{ev}(G/V)[\sigma])} \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} \right) \xrightarrow{\mathbf{K}(j(G/V)[\sigma]_*)} \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)} \mathcal{A} \right).$$

**Notation 6.2.** Let  $\mathbf{NK}(G/V; \mathcal{A}, \sigma)$  be the spectrum given by the homotopy fiber of  $\mathbf{K}(\text{ev}(G/V)[\sigma]_*) : \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} \right) \rightarrow \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)_K} \mathcal{A} \right)$ .

Let  $\mathbf{l} : \mathbf{NK}(G/V; \mathcal{A}, \sigma) \rightarrow \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} \right)$  be the canonical map of spectra. Define the map of spectra

$$\mathbf{j}(G/V; \mathcal{A}, \sigma) : \mathbf{NK}(G/V; \mathcal{A}, \sigma) \rightarrow \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)} \mathcal{A} \right)$$

to be the composite  $\mathbf{K}(j(G/V)[\sigma]_*) \circ \mathbf{l}$ .

Consider a  $G$ -map  $f : G/V \rightarrow G/W$ , where  $V$  and  $W$  are virtually cyclic groups of type I. It induces a functor  $\mathcal{G}^G(f) : \mathcal{G}^G(G/V) \rightarrow \mathcal{G}^G(G/W)$ .

It induces also a bijection

$$(6.3) \quad \text{gen}(f) : \text{gen}(Q_V) \rightarrow \text{gen}(Q_W)$$

as follows. Fix an element  $g \in G$  such that  $f(eV) = gW$ . Then  $g^{-1}Vg \subseteq W$ . The injective group homomorphism  $c(g) : V \rightarrow W$ ,  $v \mapsto g^{-1}vg$  induces an injective group homomorphism  $Q_{c(g)} : Q_V \rightarrow Q_W$  by Lemma 1.1 (vi). For  $\sigma \in \text{gen}(Q_V)$  let  $\text{gen}(f)(\sigma) \in \text{gen}(Q_W)$  be uniquely determined by the property that  $Q_{c(g)}(\sigma) = \text{gen}(f)(\sigma)^n$  for some  $n \geq 1$ . One easily checks that this is independent of the choice of  $g \in G$  with  $f(eV) = gW$  since for  $w \in W$  the conjugation homomorphism  $c(w) : W \rightarrow W$  induces the identity on  $Q_W$ . Using Lemma 1.1 (vi) it follows that  $\mathcal{G}^G(f) : \mathcal{G}^G(G/V) \rightarrow \mathcal{G}^G(G/W)$  induces functors

$$\begin{aligned} \mathcal{G}^G(f)[\sigma] : \mathcal{G}^G(G/V)[\sigma] &\rightarrow \mathcal{G}^G(G/W)[\text{gen}(f)(\sigma)]; \\ \mathcal{G}^G(f)_K : \mathcal{G}^G(G/V)_K &\rightarrow \mathcal{G}^G(G/W)_K. \end{aligned}$$

Hence we obtain a commutative diagram of maps of spectra

$$\begin{array}{ccc} \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)_K} \mathcal{A} \right) & \xrightarrow{\mathbf{K}((\mathcal{G}^G(f)_K)_*)} & \mathbf{K} \left( \int_{\mathcal{G}^G(G/W)_K} \mathcal{A} \right) \\ \mathbf{K}(\text{ev}(G/V)[\sigma]) \uparrow & & \mathbf{K}(\text{ev}(G/W)[\text{gen}(f)(\sigma)]) \uparrow \\ \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)[\sigma]} \mathcal{A} \right) & \xrightarrow{\mathbf{K}(\mathcal{G}^G(f)[\sigma]_*)} & \mathbf{K} \left( \int_{\mathcal{G}^G(G/W)[\text{gen}(f)(\sigma)]} \mathcal{A} \right) \\ \mathbf{K}(j(G/V)[\sigma]_*) \downarrow & & \mathbf{K}(j(G/W)[\text{gen}(f)(\sigma)]_*) \downarrow \\ \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)} \mathcal{A} \right) & \xrightarrow{\mathbf{K}(\mathcal{G}^G(f)_*)} & \mathbf{K} \left( \int_{\mathcal{G}^G(G/W)} \mathcal{A} \right) \end{array}$$

Thus we obtain a map of spectra

$$\mathbf{NK}(f; \mathcal{A}, \sigma) : \mathbf{NK}(G/V; \mathcal{A}, \sigma) \rightarrow \mathbf{NK}(G/W; \mathcal{A}, \text{gen}(f)(\sigma))$$

such that the following diagram of spectra commutes

$$\begin{array}{ccc} \mathbf{NK}(G/V; \mathcal{A}, \sigma) & \xrightarrow{\mathbf{NK}(f; \mathcal{A}, \sigma)} & \mathbf{NK}(G/W; \mathcal{A}, \text{gen}(f)(\sigma)) \\ \mathbf{j}(G/V; \mathcal{A}, \sigma) \downarrow & & \downarrow \mathbf{j}(G/W; \mathcal{A}, \text{gen}(f)(\sigma)) \\ \mathbf{K} \left( \int_{\mathcal{G}^G(G/V)} \mathcal{A} \right) & \xrightarrow{\mathbf{K}(\mathcal{G}^G(f)_*)} & \mathbf{K} \left( \int_{\mathcal{G}^G(G/W)} \mathcal{A} \right) \end{array}$$

Let  $\mathcal{VC}_I$  be the family of subgroups of  $G$  which consists of all finite groups and all virtually cyclic subgroups of type I. Let  $\text{Or}_{\mathcal{VC}_I}(G)$  be the full subcategory of the orbit category  $\text{Or}(G)$  consisting of objects  $G/V$  for which  $V$  belongs to  $\mathcal{VC}_I$ . Define a functor

$$\mathbf{NK}_{\mathcal{A}}^G: \text{Or}_{\mathcal{VC}_I}(G) \rightarrow \text{Spectra}$$

as follows. It sends  $G/H$  for a finite subgroup  $H$  to the trivial spectrum and  $G/V$  for a virtually cyclic subgroup  $V$  of type I to  $\bigvee_{\sigma \in \text{gen}(Q_V)} \mathbf{NK}(G/V; \mathcal{A}, \sigma)$ . Consider a map  $f: G/V \rightarrow G/W$ . If  $V$  or  $W$  is finite, it is sent to the trivial map. Suppose that both  $V$  and  $W$  are infinite virtually cyclic subgroups of type I. Then it is sent to the wedge of the two maps

$$\begin{aligned} \mathbf{NK}(f; \mathcal{A}, \sigma_1): \mathbf{NK}(G/V; \mathcal{A}, \sigma_1) &\rightarrow \mathbf{NK}(G/W; \mathcal{A}, \text{gen}(f)(\sigma_1)); \\ \mathbf{NK}(f; \mathcal{A}, \sigma_2): \mathbf{NK}(G/V; \mathcal{A}, \sigma_2) &\rightarrow \mathbf{NK}(G/W; \mathcal{A}, \text{gen}(f)(\sigma_2)), \end{aligned}$$

for  $\text{gen}(Q_V) = \{\sigma_1, \sigma_2\}$ .

The restriction of the covariant  $\text{Or}(G)$ -spectrum  $\mathbf{K}_{\mathcal{A}}^G: \text{Or}(G) \rightarrow \text{Spectra}$  to  $\text{Or}_{\mathcal{VC}_I}(G)$  will be denoted by the same symbol

$$\mathbf{K}_{\mathcal{A}}^G: \text{Or}_{\mathcal{VC}_I}(G) \rightarrow \text{Spectra}.$$

The wedge of the maps  $\mathbf{j}(G/V; \mathcal{A}, \sigma_1)$  and  $\mathbf{j}(G/V; \mathcal{A}, \sigma_2)$  for  $V$  a virtually cyclic subgroup of  $G$  of type I yields a map of spectra  $\mathbf{NK}_{\mathcal{A}}^G(G/V) \rightarrow \mathbf{K}_{\mathcal{A}}^G(G/V)$ . Thus we obtain a transformation of functors from  $\text{Or}_{\mathcal{VC}_I}(G)$  to  $\text{Spectra}$

$$(6.4) \quad \mathbf{b}_{\mathcal{A}}^G: \mathbf{NK}_{\mathcal{A}}^G \rightarrow \mathbf{K}_{\mathcal{A}}^G.$$

## 7. SPLITTING THE RELATIVE ASSEMBLY MAP AND IDENTIFYING THE RELATIVE TERM

Let  $X$  be a  $G$ -space. It defines a contravariant  $\text{Or}(G)$ -space  $O^G(X)$ , i.e., a contravariant functor from  $\text{Or}(G)$  to the category of spaces, by sending  $G/H$  to the  $H$ -fixed point set  $\text{map}_G(G/H, X) = X^H$ . Let  $O^G(X)_+$  be the pointed  $\text{Or}(G)$ -space, where  $O^G(X)_+(G/H)$  is obtained from  $O^G(X)(G/H)$  by adding an extra base point. If  $f: X \rightarrow Y$  is a  $G$ -map, we obtain a natural transformation  $O^G(f)_+: O^G(X)_+ \rightarrow O^G(Y)_+$ .

Let  $\mathbf{E}$  be a covariant  $\text{Or}(G)$ -spectrum, i.e., a covariant functor from  $\text{Or}(G)$  to the category of spectra. Fix a  $G$ -space  $Z$ . Define the covariant  $\text{Or}(G)$ -spectrum

$$\mathbf{E}_Z: \text{Or}(G) \rightarrow \text{Spectra}$$

as follows. It sends an object  $G/H$  to the spectrum  $O^G(G/H \times Z)_+ \wedge_{\text{Or}(G)} \mathbf{E}$ , where  $\wedge_{\text{Or}(G)}$  is the wedge product of a pointed spaces and a spectrum over a category (see [5, Section 1], where  $\wedge_{\text{Or}(G)}$  is denoted by  $\otimes_{\text{Or}(G)}$ ). The obvious identification of  $O^G(G/H)_+(?) \wedge_{\text{Or}(G)} \mathbf{E}(?)$  with  $\mathbf{E}(G/H)$  and the projection  $G/H \times Z \rightarrow G/H$  yields a natural transformation of covariant functors  $\text{Or}(G) \rightarrow \text{Spectra}$

$$(7.1) \quad \mathbf{a}: \mathbf{E}_Z \rightarrow \mathbf{E}.$$

**Lemma 7.2.** *Given a  $G$ -space  $X$ , there exists an isomorphism of spectra*

$$\mathbf{u}^G(X): O^G(X \times Z)_+ \wedge_{\text{Or}(G)} \mathbf{E} \xrightarrow{\cong} O^G(X)_+ \wedge_{\text{Or}(G)} \mathbf{E}_Z,$$

which is natural in  $X$  and  $Z$ .

*Proof.* The smash product  $\wedge_{\text{Or}(G)}$  is associative, i.e., there is a natural isomorphism of spectra

$$\begin{aligned} (O^G(X)_+(?) \wedge_{\text{Or}(G)} O^G(?? \times Z)_+(?)) \wedge_{\text{Or}(G)} \mathbf{E}(?) \\ \xrightarrow{\cong} O^G(X)_+(?) \wedge_{\text{Or}(G)} (O^G(?? \times Z)_+(?) \wedge_{\text{Or}(G)} \mathbf{E}(?)). \end{aligned}$$

There is a natural isomorphism of covariant  $\text{Or}(G)$ -spaces

$$O^G(X \times Z)_+ \xrightarrow{\cong} O^G(X)_+(?) \wedge_{\text{Or}(G)} O^G(? \times Z)_+$$

which evaluated at  $G/H$  sends  $\alpha: G/H \rightarrow X \times Z$  to  $(\text{pr}_1 \circ \alpha) \wedge (\text{id}_{G/H} \times (\text{pr}_2 \circ \alpha))$  if  $\text{pr}_i$  is the projection onto the  $i$ -th factor of  $X \times Z$ . The inverse evaluated at  $G/H$  sends  $(\beta_1: G/H \rightarrow X) \wedge (\beta_2: G/H \rightarrow G/H \times Z)$  to  $(\beta_1 \times \text{id}_Z) \circ \beta_2$ . The composite of these two isomorphisms yield the desired isomorphism  $\mathbf{u}^G(X)$ .  $\square$

If  $\mathcal{F}$  is a family of subgroups of the group  $G$ , e.g.,  $\mathcal{V}\mathcal{C}_I$  or the family  $\mathcal{F}_{\text{in}}$  of finite subgroups, then we denote by  $E_{\mathcal{F}}(G)$  the classifying space of  $\mathcal{F}$ . (For a survey on these spaces we refer for instance to [16].) Let  $\underline{E}G$  denote the classifying space for proper  $G$ -actions, or in other words, a model for  $E_{\mathcal{F}_{\text{in}}}(G)$ . If we restrict a covariant  $\text{Or}(G)$  spectrum  $\mathbf{E}$  to  $\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)$ , we will denote it by the same symbol  $\mathbf{E}$  and analogously for  $O^G(X)$ .

**Lemma 7.3.** *Let  $\mathcal{F}$  be a family of subgroups. Let  $X$  be a  $G$ -CW-complex whose isotropy groups belong to  $\mathcal{F}$ . Let  $\mathbf{E}$  be a covariant  $\text{Or}(G)$ -spectrum. Then there is a natural homeomorphism of spectra*

$$O^G(X)_+ \wedge_{\text{Or}_{\mathcal{F}}(G)} \mathbf{E} \xrightarrow{\cong} O^G(X)_+ \wedge_{\text{Or}(G)} \mathbf{E}.$$

*Proof.* Let  $I: \text{Or}_{\mathcal{F}}(G) \rightarrow \text{Or}(G)$  be the inclusion. The claim follows from the adjunction of induction  $I_*$  and restriction  $I^*$ , see [5, Lemma 1.9], and the fact that for the  $\text{Or}(G)$ -space  $O^G(X)$  the canonical map  $I_* I^* O^G(X) \rightarrow O^G(X)$  is a homeomorphism of  $\text{Or}(G)$ -spaces.  $\square$

In the sequel we will abbreviate  $\mathbf{E}_{\underline{E}G}$  by  $\underline{\mathbf{E}}$ .

**Lemma 7.4.** *Let  $\mathbf{E}$  be a covariant  $\text{Or}(G)$ -spectrum. Let  $f: \underline{E}G \rightarrow E_{\mathcal{V}\mathcal{C}_I}(G)$  be a  $G$ -map. (It is unique up to  $G$ -homotopy.) Then there is an up to homotopy commutative diagram of spectra whose upper horizontal map is a weak equivalence*

$$\begin{array}{ccc} O^G(E_{\mathcal{V}\mathcal{C}_I}(G)) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \underline{\mathbf{E}} & \xrightarrow{\cong} & O^G(\underline{E}G) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} \\ & \searrow \text{id} \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{a} & \swarrow O^G(f) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \text{id} \\ & O^G(E_{\mathcal{V}\mathcal{C}_I}(G)) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} & \end{array}$$

*Proof.* From Lemma 7.2 we obtain a commutative diagram with an isomorphism as horizontal map

$$\begin{array}{ccc} O^G(E_{\mathcal{V}\mathcal{C}_I}(G)) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \underline{\mathbf{E}} & \xrightarrow{\cong} & O^G(E_{\mathcal{V}\mathcal{C}_I}(G) \times \underline{E}G) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} \\ & \searrow \text{id} \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{a} & \swarrow O^G(\text{pr}_1) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \text{id} \\ & O^G(E_{\mathcal{V}\mathcal{C}_I}(G)) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} & \end{array}$$

where  $\text{pr}_1: E_{\mathcal{V}\mathcal{C}_I}(G) \times \underline{E}G \rightarrow E_{\mathcal{V}\mathcal{C}_I}(G)$  is the obvious projection. The projection  $\text{pr}_2: E_{\mathcal{V}\mathcal{C}_I}(G) \times \underline{E}G \rightarrow \underline{E}G$  is a  $G$ -homotopy equivalence and its composite with  $f: \underline{E}G \rightarrow E_{\mathcal{V}\mathcal{C}_I}(G)$  is  $G$ -homotopic to  $\text{pr}_1$ . Hence the following diagram of spectra commutes up to  $G$ -homotopy and has a weak equivalence as horizontal map.

$$\begin{array}{ccc} O^G(E_{\mathcal{V}\mathcal{C}_I}(G) \times \underline{E}G) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} & \xrightarrow[\simeq]{O^G(\text{pr}_2) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \text{id}} & O^G(\underline{E}G) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} \\ & \searrow O^G(\text{pr}_1) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \text{id} & \swarrow O^G(f) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \text{id} \\ & O^G(E_{\mathcal{V}\mathcal{C}_I}(G)) \wedge_{\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)} \mathbf{E} & \end{array}$$

Putting these two diagrams together, finishes the proof of Lemma 7.4  $\square$

If  $\mathbf{E}$  is the functor  $\mathbf{K}_A^G$  defined in (6.1) and  $Z = \underline{E}G$ , we will write  $\underline{\mathbf{K}}_A^G$  for  $\underline{\mathbf{E}} = \mathbf{E}_{\underline{E}G}$ .

**Lemma 7.5.** *Let  $H$  be a finite group or an infinite virtually cyclic group of type I. Then the map of spectra (see (6.4) and (7.1))*

$$\mathbf{a}(G/H) \vee \mathbf{b}(G/H): \underline{\mathbf{K}}_A^G(G/H) \vee \mathbf{NK}_A^G(G/H) \rightarrow \mathbf{K}_A^G(G/H)$$

is a weak equivalence.

*Proof.* Given an infinite cyclic subgroup  $V \subseteq G$  of type I, we next construct the following up to homotopy commutative diagram of spectra whose vertical arrows are all weak homotopy equivalences for  $K = K_V$  and  $Q = Q_V$ . Let  $i_V: V \rightarrow G$  be the inclusion and  $p_V: V \rightarrow Q_V := V/K_V$  be the projection.

$$\begin{array}{c}
 \underline{\mathbf{K}}_A^G(G/V) \\
 \downarrow (1) \text{ id} \\
 O^G(G/V \times \underline{E}G)_+ \wedge_{\text{Or}(G)} \mathbf{K}_A^G \\
 \downarrow (2) \cong \\
 O^G((i_V)_*(i_V)^*\underline{E}G)_+ \wedge_{\text{Or}(G)} \mathbf{K}_A^G \\
 \downarrow (3) \cong \\
 O^V((i_V)^*\underline{E}G)_+ \wedge_{\text{Or}(V)} (i_V)^*\mathbf{K}_A^G \\
 \downarrow (4) \simeq \\
 O^V((p_V)^*EQ_V)_+ \wedge_{\text{Or}(V)} (i_V)^*\mathbf{K}_A^G \\
 \downarrow (5) \cong \\
 O^{Q_V}(EQ_V)_+ \wedge_{\text{Or}(Q_V)} (p_V)_!(i_V)^*\mathbf{K}_A^G \\
 \downarrow (6) \cong \\
 (EQ_V)_+ \wedge_{Q_V} (p_V)_!(i_V)^*\mathbf{K}_A^G(Q_V/1) \\
 \downarrow (7) \cong \\
 (EQ_V)_+ \wedge_{Q_V} \mathbf{K}_A^G(G/K) \\
 \downarrow (8) \cong \\
 T_{\mathbf{K}(R_\sigma)}: \mathbf{K}_A^G(G/K) \rightarrow \mathbf{K}_A^G(G/K)
 \end{array}
 \begin{array}{l}
 \xrightarrow{\mathbf{a}(G/V)} \\
 \xrightarrow{\mathbf{a}'(G/V)}
 \end{array}
 \mathbf{K}_A^G(G/V)$$

We first explain the vertical arrow starting at the top. The first one is the identity by definition. The second one comes from the  $G$ -homeomorphism  $G/V \times \underline{E}G \xrightarrow{\cong} (i_V)_*(i_V)^*\underline{E}G = G \times_V \underline{E}G$  sending  $(gV, x)$  to  $(g, g^{-1}x)$ . The third one comes from the adjunction of induction  $(i_V)_*$  and restriction  $i_V^*$ , see [5, Lemma 1.9]. The fourth one comes from the fact that  $p_V^*EQ$  and  $i_V^*\underline{E}G$  are both models for  $\underline{E}V$  and hence are  $V$ -homotopy equivalent. The fifth one comes from the adjunction of restriction  $p_V^*$  with coinduction  $(p_V)_!$ , see [5, Lemma 1.9]. The sixth one comes from the fact that  $EQ$  is a free  $Q$ -CW-complex and Lemma 7.3 applied to the family consisting of one subgroup, namely the trivial subgroup. The seventh one comes from the identification  $(p_V)_!(i_V)^*\mathbf{K}_A^G(Q_V/1) = (i_V)^*\mathbf{K}_A^G(V/K) = \mathbf{K}_A^G(G/K)$ . The last one

comes from the obvious homeomorphism if we use for  $EQ_V$  the standard model with  $\mathbb{R}$  as underlying  $Q_V = \mathbb{Z}$ -space. The arrow  $\mathbf{a}'(G/V)$  is induced by the upper triangle in (5.9), which commutes (strictly). One easily checks that the diagram above commutes.

Here is a short explanation on the diagram above. The map  $\mathbf{a}(G/V)$  is basically given by the projection  $G/V \times \underline{EG} \rightarrow G/V$ . Following the equivalences (1) through (5), this corresponds to projecting  $EQ_V$  to a point. On the domain of equivalence (8), this corresponds to projecting  $EQ_V$  to a point and to take the inclusion-induced map  $\mathbf{K}_A^G(G/K) \rightarrow \mathbf{K}_A^G(G/V)$  on the other factor. But this is precisely the definition of the map  $\mathbf{a}'(G/V)$ .

From the diagram (5.9) (including the preferred equivalences and the fact that a natural isomorphism of functors induces a preferred homotopy after applying the  $K$ -theory spectrum) we obtain the following diagram of spectra which commutes up to homotopy and has weak homotopy equivalences as vertical arrows.

$$\begin{array}{ccc}
T_{\mathbf{K}(R_\sigma)}: \mathbf{K}_A^G(G/K) \rightarrow \mathbf{K}_A^G(G/K) & \xrightarrow{\mathbf{a}'(G/V)} & \mathbf{K}_A^G(G/V) \\
\uparrow \simeq & & \uparrow \simeq \\
T_{\mathbf{K}(\Phi)}: \mathbf{K}(\int_{\widehat{K}} \mathcal{A}) \rightarrow \mathbf{K}(\int_{\widehat{K}} \mathcal{A}) & \xrightarrow{\mathbf{a}''(G/V)} & \mathbf{K}(\int_{\widehat{V}} \mathcal{A}) \\
\uparrow \text{id} & & \uparrow \cong \\
T_{\mathbf{K}(\phi)}: \mathbf{K}(\mathcal{B}) \rightarrow \mathbf{K}(\mathcal{B}) & \xrightarrow{\mathbf{a}_B} & \mathbf{K}(\int_{\widehat{Q}} \mathcal{B})
\end{array}$$

We obtain from the diagram (5.8) the following commutative diagram of spectra with weak homotopy equivalences as vertical arrows.

$$\begin{array}{ccc}
\mathbf{NK}_A^G(G/V) & \xrightarrow{\mathbf{b}(G/V)} & \mathbf{K}_A^G(G/V) \\
\uparrow \simeq & & \uparrow \simeq \\
\mathbf{NK}(\mathcal{B}) & \xrightarrow{\mathbf{b}_B} & \mathbf{K}(\int_{\widehat{Q}_V} \mathcal{B})
\end{array}$$

We conclude from the three diagrams of spectra above that

$$\mathbf{a}(G/V) \vee \mathbf{b}(G/V): \mathbf{K}_A^G(G/V) \vee \mathbf{NK}_A^G(G/V) \rightarrow \mathbf{K}_A^G(G/V)$$

is a weak homotopy of spectra if and only if

$$\mathbf{a}_B \vee \mathbf{b}_B: T_{\mathbf{K}(\phi)}: \mathbf{K}(\mathcal{B}) \rightarrow \mathbf{K}(\mathcal{B}) \vee \mathbf{NK}(\mathcal{B}) \rightarrow \mathbf{K}(\int_{\widehat{Q}_V} \mathcal{B})$$

is a weak homotopy equivalence. Since this is just the assertion of Theorem 4.2, the claim of Lemma 7.5 follows in the case, where  $H$  is an infinite virtually cyclic group of type I.

It remains to consider the case, where  $H$  is finite. Then  $\mathbf{NK}_A^G(G/V)$  is by definition the trivial spectrum. Hence it remains to show for a finite subgroup  $H$  of  $G$  that  $\mathbf{a}(G/H): \mathbf{K}_A^G(G/H) \rightarrow \mathbf{K}_A^G(G/H)$  is a weak homotopy equivalence. This follows from the fact that the projection  $G/H \times \underline{EG} \rightarrow G/H$  is a  $G$ -homotopy equivalence for finite  $H$ .  $\square$

Recall that any covariant  $\text{Or}(G)$ -spectrum  $\mathbf{E}$  determines a  $G$ -homology theory  $H_*^G(-; \mathbf{E})$  satisfying  $H_n^G(G/H; \mathbf{E}) = \pi_n(\mathbf{E}(G/H))$ , namely put (see [5])

$$(7.6) \quad H_*^G(X; \mathbf{E}) := \pi_*(O^G(X) \wedge_{\text{Or}(G)} \mathbf{E}).$$

In the sequel we often follow the convention in the literature to abbreviate  $\underline{EG} := E_{\mathcal{VC}}(G)$  for the family  $\mathcal{VC}$  of virtually cyclic subgroups. Recall that for two families of subgroups  $\mathcal{F}_1$  and  $\mathcal{F}_2$  with  $\mathcal{F}_1 \subseteq \mathcal{F}_2$  there is up to  $G$ -homotopy one  $G$ -map  $f: E_{\mathcal{F}_1}(G) \rightarrow E_{\mathcal{F}_2}(G)$ . We will define  $H_n(E_{\mathcal{F}_1}(G) \rightarrow E_{\mathcal{F}_2}(G); \mathbf{K}_R^G) := H_n(\text{cyl}(f), E_{\mathcal{F}_1}(G); \mathbf{K}_R^G)$ , where  $(\text{cyl}(f), E_{\mathcal{F}_1}(G))$  is the  $G$ -pair coming from the mapping cylinder of  $f$ .

Notice that  $\mathbf{NK}_A^G$  is defined only over  $\text{Or}_{\mathcal{VC}_I}(G)$ . It can be extended to a spectrum over  $\text{Or}(G)$  by applying the coinduction functor (see [5, Definition 1.8]) associated to the inclusion  $\text{Or}_{\mathcal{VC}_I}(G) \rightarrow \text{Or}(G)$  so that the  $G$ -homology theory  $H_n^G(-; \mathbf{NK}_A^G)$  makes sense for all pairs  $(X, A)$  of  $G$ -CW-complexes. Moreover,  $H_n^G(X; \mathbf{NK}_A^G)$  can be identified with  $\pi_n(O^G(X) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{NK}_A^G)$  for all  $G$ -CW-complexes  $X$ .

The remainder of this section is devoted to the proof of Theorem 0.1. Its proof will need the following result taken from [6, Remark 1.6].

**Theorem 7.7** (Passage from  $\mathcal{VC}_I$  to  $\mathcal{VC}$  in  $K$ -theory). *The relative assembly map*

$$H_n^G(E_{\mathcal{VC}_I}(G); \mathbf{K}_A^G) \xrightarrow{\cong} H_n^G(\underline{EG}; \mathbf{K}_A^G)$$

is bijective for all  $n \in \mathbb{Z}$ .

Hence we only have to deal in the proof of Theorem 0.1 with the passage from  $\mathcal{F}_I$  to  $\mathcal{VC}_I$ .

*Proof of Theorem 0.1.* From Lemma 7.5 and [5, Lemma 4.6], we obtain a weak equivalence of spectra

$$\begin{aligned} \text{id} \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} (\mathbf{a} \vee \mathbf{b}): O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} (\underline{\mathbf{K}}_A^G \vee \mathbf{NK}_A^G) \\ \rightarrow O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{K}_A^G. \end{aligned}$$

Hence we obtain a weak equivalence of spectra

$$\begin{aligned} (\text{id} \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{a}) \vee (\text{id} \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{b}): \\ (O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \underline{\mathbf{K}}_A^G) \vee (O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{NK}_A^G) \\ \rightarrow O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{K}_A^G. \end{aligned}$$

If we combine this with Lemma 7.4 we obtain a weak equivalence of spectra

$$\begin{aligned} (f \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \text{id}) \vee (\text{id} \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{b}): \\ (O^G(\underline{EG}) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{K}_A^G) \vee (O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{NK}_A^G) \\ \rightarrow O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{K}_A^G. \end{aligned}$$

Using Lemma 7.3 this yields a natural weak equivalence of spectra

$$\begin{aligned} (f \wedge_{\text{Or}(G)} \text{id}) \vee \mathbf{b}': \\ (O^G(\underline{EG}) \wedge_{\text{Or}(G)} \mathbf{K}_A^G) \vee (O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{NK}_A^G) \\ \rightarrow O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}(G)} \mathbf{K}_A^G, \end{aligned}$$

where  $\mathbf{b}'$  comes from  $\text{id} \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{b}$ . If we take homotopy groups, we obtain for every  $n \in \mathbb{Z}$  an isomorphism

$$\begin{aligned} H_n^G(f; \mathbf{K}_A^G) \oplus \pi_n(\mathbf{b}'): H_n^G(\underline{EG}; \mathbf{K}_A^G) \oplus \pi_n(O^G(E_{\mathcal{VC}_I}(G)) \wedge_{\text{Or}_{\mathcal{VC}_I}(G)} \mathbf{NK}_A^G) \\ \xrightarrow{\cong} H_n(E_{\mathcal{VC}_I}(G); \mathbf{K}_A^G). \end{aligned}$$

We have already explained above that  $H_n^G(E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G)$  can be identified with  $\pi_n(O^G(E_{\mathcal{V}C_I}(G) \wedge_{\text{Or}_{\mathcal{V}C_I}(G)} \mathbf{NK}_{\mathcal{A}}^G))$ . Since by construction  $\mathbf{NK}_{\mathcal{A}}^G(G/H)$  is the trivial spectrum for finite  $H$  and all isotropy groups of  $\underline{E}G$  are finite, we conclude  $H_n^G(\underline{E}G; \mathbf{NK}_{\mathcal{A}}^G) = 0$  for all  $n \in \mathbb{Z}$  from Lemma 7.3. We derive from the long exact sequence of  $f: \underline{E}(G) \rightarrow E_{\mathcal{V}C_I}(G)$  that the canonical map

$$H_n^G(E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G) \xrightarrow{\cong} H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G)$$

is bijective for all  $n \in \mathbb{Z}$ . Hence we obtain for all  $n \in \mathbb{Z}$  a natural isomorphism

$$\begin{aligned} H_n^G(f; \mathbf{K}_{\mathcal{A}}^G) \oplus b_n: H_n^G(\underline{E}G; \mathbf{K}_{\mathcal{A}}^G) \oplus H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G) \\ \xrightarrow{\cong} H_n^G(E_{\mathcal{V}C_I}(G); \mathbf{K}_{\mathcal{A}}^G). \end{aligned}$$

We conclude from the long exact homology sequence associated to  $f: \underline{E}G \rightarrow E_{\mathcal{V}C_I}(G)$  that the map

$$H_n^G(f; \mathbf{K}_{\mathcal{A}}^G): H_n^G(\underline{E}G; \mathbf{K}_{\mathcal{A}}^G) \rightarrow H_n^G(E_{\mathcal{V}C_I}(G); \mathbf{K}_{\mathcal{A}}^G)$$

is split injective, there is a natural splitting

$$H_n^G(E_{\mathcal{V}C_I}(G); \mathbf{K}_{\mathcal{A}}^G) \xrightarrow{\cong} H_n^G(\underline{E}G; \mathbf{K}_{\mathcal{A}}^G) \oplus H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{K}_{\mathcal{A}}^G),$$

and there exists a natural isomorphism which is induced by the natural transformation  $\mathbf{b}: \mathbf{NK}_{\mathcal{A}}^G \rightarrow \mathbf{K}_{\mathcal{A}}^G$  of spectra over  $\text{Or}_{\mathcal{V}C_I}(G)$

$$H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_{\mathcal{A}}^G) \xrightarrow{\cong} H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{K}_{\mathcal{A}}^G).$$

Now Theorem 0.1 follows from Theorem 7.7.  $\square$

## 8. INVOLUTIONS AND VANISHING OF TATE COHOMOLOGY

**8.1. Involutions on  $K$ -theory spectra.** Let  $\mathcal{A} = (\mathcal{A}, I)$  be an additive  $G$ -category with involution, i.e., an additive  $G$ -category  $\mathcal{A}$  together with a contravariant functor  $I: \mathcal{A} \rightarrow \mathcal{A}$  satisfying  $I \circ I = \text{id}_{\mathcal{A}}$  and  $I \circ R_g = R_g \circ I$  for all  $g \in G$ . Examples coming from twisted group rings, or more generally crossed product rings equipped with involutions twisted by orientation homomorphisms are discussed in [1, Section 8].

In the sequel we denote for a category  $\mathcal{C}$  its *opposite* category by  $\mathcal{C}^{\text{op}}$ . It has the same objects as  $\mathcal{C}$ . A morphism in  $\mathcal{C}^{\text{op}}$  from  $x$  to  $y$  is a morphism  $y \rightarrow x$  in  $\mathcal{C}$ . Obviously we can and will identify  $(\mathcal{C}^{\text{op}})^{\text{op}} = \mathcal{C}$ .

Next we define a covariant functor

$$(8.1) \quad I(G/H): \int_{\mathcal{G}^G(G/H)} \mathcal{A} \rightarrow \left( \int_{\mathcal{G}^G(G/H)} \mathcal{A} \right)^{\text{op}}.$$

It is defined to extend the involution

$$\coprod_{x \in \mathcal{G}^G(G/H)} I: \coprod_{x \in \mathcal{G}^G(G/H)} \mathcal{A} \rightarrow \left( \coprod_{x \in \mathcal{G}^G(G/H)} \mathcal{A} \right)^{\text{op}}$$

and to send a structural morphism  $T_g: (g_1H, A \cdot g) \rightarrow (g_2H, A)$  to  $T_{g^{-1}}: (g_2H, I(A)) \rightarrow (g_1H, I(A) \cdot g)$ . One easily checks that  $I(G/H) \circ I(G/H) = \text{id}$ .

Notice that there is a canonical identification  $\mathbf{K}(\mathcal{B}^{\text{op}}) = \mathbf{K}(\mathcal{B})$  for every additive category  $\mathcal{B}$ . Hence  $I(G/H)$  induces a map of spectra

$$\mathbf{i}(G/H) = \mathbf{K}(I(G/H)): \mathbf{K} \left( \int_{\mathcal{G}^G(G/H)} \mathcal{A} \right) \rightarrow \mathbf{K} \left( \int_{\mathcal{G}^G(G/H)} \mathcal{A} \right)$$

such that  $\mathbf{i}(G/H) \circ \mathbf{i}(G/H) = \text{id}$ . Let  $\mathbb{Z}/2\text{-Spectra}$  be the category of spectra with a (strict)  $\mathbb{Z}/2$ -operation. Thus the functor  $\mathbf{K}_R^G$  becomes a functor

$$(8.2) \quad \mathbf{K}_R^G: \text{Or}(G) \rightarrow \mathbb{Z}/2\text{-Spectra}.$$

Consider an infinite virtually cyclic subgroup  $V \subseteq G$  and a fixed generator  $\sigma \in Q_V$ . The functor  $I(G/V)$  of (8.1) induces functors

$$\begin{aligned} I(G/H)[\sigma]: \int_{\mathcal{G}^{\mathcal{G}(G/H)[\sigma]}} \mathcal{A} &\rightarrow \left( \int_{\mathcal{G}^{\mathcal{G}(G/H)[\sigma^{-1}]}} \mathcal{A} \right)^{\text{op}}; \\ I(G/H)_K: \int_{\mathcal{G}^{\mathcal{G}(G/H)_K}} \mathcal{A} &\rightarrow \left( \int_{\mathcal{G}^{\mathcal{G}(G/H)_K}} \mathcal{A} \right)^{\text{op}}. \end{aligned}$$

Since  $\text{ev}(G/V)[\sigma^{-1}]_* \circ I(G/V)[\sigma] = I(G/V)_K \circ \text{ev}(G/V)[\sigma]$  and  $j(G/V)[\sigma^{-1}]_* \circ I(G/V)[\sigma] = I(G/V) \circ j(G/V)[\sigma]_*$  holds, we obtain a commutative diagram of spectra

$$\begin{array}{ccccc} \mathbf{K} \left( \int_{\mathcal{G}^{\mathcal{G}(G/V)_K}} \mathcal{A} \right) & \xleftarrow{\mathbf{K}(\text{ev}(G/V)[\sigma]_*)} & \mathbf{K} \left( \int_{\mathcal{G}^{\mathcal{G}(G/V)[\sigma]}} \mathcal{A} \right) & \xrightarrow{\mathbf{K}(j(G/V)[\sigma]_*)} & \mathbf{K} \left( \int_{\mathcal{G}^{\mathcal{G}(G/V)}} \mathcal{A} \right) \\ \downarrow \mathbf{K}(I(G/V)_K) & & \downarrow \mathbf{K}(I(G/V)[\sigma]) & & \downarrow \mathbf{K}(I(G/V)) \\ \mathbf{K} \left( \int_{\mathcal{G}^{\mathcal{G}(G/V)_K}} \mathcal{A} \right) & \xleftarrow{\mathbf{K}(\text{ev}(G/V)[\sigma^{-1}]_*)} & \mathbf{K} \left( \int_{\mathcal{G}^{\mathcal{G}(G/V)[\sigma^{-1}]}} \mathcal{A} \right) & \xrightarrow{\mathbf{K}(j(G/V)[\sigma^{-1}]_*)} & \mathbf{K} \left( \int_{\mathcal{G}^{\mathcal{G}(G/V)}} \mathcal{A} \right) \end{array}$$

Since  $I(G/H)[\sigma^{-1}] \circ I(G/H)[\sigma] = \text{id}$  and  $I(G/H)_K \circ I(G/H)_K = \text{id}$  holds, we obtain a  $\mathbb{Z}/2$ -operation on  $\mathbf{NK}_A^G$  and hence a functor

$$(8.3) \quad \mathbf{NK}_A^G: \text{Or}(G) \rightarrow \mathbb{Z}/2\text{-Spectra},$$

and we conclude:

**Lemma 8.4.** *The transformation  $\mathbf{b}: \mathbf{NK}_A^G \rightarrow \mathbf{K}_A^G$  of  $\text{Or}_{\mathcal{VC}_I}(G)$ -spectra is compatible with the  $\mathbb{Z}/2$ -actions.*

## 8.2. Orientable virtually cyclic subgroups of type I.

**Definition 8.5** (Orientable virtually cyclic subgroups of type I). *Given a group  $G$ , we say that the infinite virtually cyclic subgroups of type I of  $G$  are orientable if there is for every virtually cyclic subgroup  $V$  of type I a choice  $\sigma_V$  of a generator of the infinite cyclic group  $Q_V$  with the following property: Whenever  $V$  and  $V'$  are infinite virtually cyclic subgroups of type I, and  $f: V \rightarrow V'$  is an inclusion or a conjugation by some element of  $G$ , then the map  $Q_f: Q_V \rightarrow Q_{V'}$  sends  $\sigma_V$  to a positive multiple of  $\sigma_{V'}$ . Such a choice of elements  $\{\sigma_V \mid V \in \mathcal{VC}_I\}$  is called an orientation.*

**Lemma 8.6.** *Suppose that the virtually cyclic subgroups of type I of  $G$  are orientable. Then all infinite virtually cyclic subgroups of  $G$  are of type I, and the fundamental group  $\mathbb{Z} \rtimes \mathbb{Z}$  of the Klein bottle is not a subgroup of  $G$ .*

*Proof.* Suppose that  $G$  contains an infinite virtually cyclic subgroup  $V$  of type II. Then  $Q_V$  is the infinite dihedral group. Its commutator  $[Q_V, Q_V]$  is infinite cyclic. Let  $W$  be the preimage of the commutator  $[Q_V, Q_V]$  under the canonical projection  $p_V: V \rightarrow Q_V$ . There exists an element  $y \in Q_V$  such that conjugation with  $y$  induces  $-\text{id}$  on  $[Q_V, Q_V]$ . Obviously  $W$  is an infinite virtually cyclic group of type I, and the restriction of  $p_V$  to  $W$  is the canonical map  $p_W: W \rightarrow Q_W = [Q_V, Q_V]$ . Choose an element  $x \in V$  with  $p_V(x) = y$ . Conjugation with  $x$  induces an automorphism of  $W$  which induces  $-\text{id}$  on  $Q_W$ . Hence the virtually cyclic subgroups of type I of  $G$  are not orientable.

The statement about the Klein bottle is obvious.  $\square$

For the notions of a CAT(0)-group and of a hyperbolic group we refer for instance to [4, 10, 12]. The fundamental group of a closed Riemannian manifold is hyperbolic

if the sectional curvature is strictly negative, and is a CAT(0)-group if the sectional curvature is non-positive.

**Lemma 8.7.** *Let  $G$  be a hyperbolic group. Then the infinite virtually cyclic subgroups of type I of  $G$  are orientable, if and only if all infinite virtually cyclic subgroups of  $G$  are of type I.*

*Proof.* The “only if”-statement follows from Lemma 8.6. To prove the “if”-statement, assume that all infinite virtually cyclic subgroups of  $G$  are of type I.

By [21, Example 3.6], every hyperbolic group satisfies the condition  $(NM_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$ , i.e., every infinite virtually cyclic subgroup  $V$  is contained in unique maximal one  $V_{\text{max}}$  and the normalizer of  $V_{\text{max}}$  satisfies  $NV_{\text{max}} = V_{\text{max}}$ . Let  $\mathcal{M}$  be a complete system of representatives of the conjugacy classes of maximal infinite virtually cyclic subgroups. Since by assumption  $V \in \mathcal{M}$  is of type I, we can fix a generator  $\sigma_V \in Q_V$  for each  $V \in \mathcal{M}$ .

Consider any infinite virtually cyclic subgroup  $W$  of  $G$  type I. Choose  $g \in G$  and  $V \in \mathcal{M}$  such that  $gWg^{-1} \subseteq V$ . Then conjugation with  $g$  induces an injection  $Q_{c(g)}: Q_W \rightarrow Q_V$  by Lemma 1.1 (vi). We equip  $W$  with the generator  $\sigma_W \in Q_W$  for which there exists an integer  $n \geq 1$  with  $Q_{c(g)}(\sigma_W) = (\sigma_V)^n$ . This is independent of the choice of  $g$  and  $V$ : For every  $g \in G$  and  $V \in \mathcal{M}$  with  $|gVg^{-1} \cap W| = \infty$ , the condition  $(NM_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$  implies that  $g$  belongs to  $V$  and conjugation with an element  $g \in V$  induces the identity on  $Q_V$ .  $\square$

**Lemma 8.8.** *Let  $G$  be a CAT(0)-group. Then the infinite virtually cyclic subgroups of type I of  $G$  are orientable if and only if all infinite virtually cyclic subgroups of  $G$  are of type I and the fundamental group  $\mathbb{Z} \rtimes \mathbb{Z}$  of the Klein bottle is not a subgroup of  $G$ .*

*Proof.* Because of Lemma 8.6 it suffices to construct for a CAT(0)-group an orientation for its infinite virtually cyclic subgroups of type I, provided that all infinite virtually cyclic subgroups of  $G$  are of type I and the fundamental group  $\mathbb{Z} \rtimes \mathbb{Z}$  of the Klein bottle is not a subgroup of  $G$ .

Consider on the set of infinite virtually cyclic subgroups of type I of  $G$  the relation  $\sim$ , where we put  $V_1 \sim V_2$  if and only if there exists an element  $g \in G$  with  $|gV_1g^{-1} \cap V_2| = \infty$ . This is an equivalence relation since for any infinite virtually cyclic group  $V$  and elements  $v_1, v_2 \in V$  of infinite order we can find integers  $n_1, n_2$  with  $v_1^{n_1} = v_2^{n_2}$ ,  $n_1 \neq 0$  and  $n_2 \neq 0$ . Choose a complete system of representatives  $\mathcal{S}$  for the classes under  $\sim$ . For each element  $V \in \mathcal{S}$  we choose an orientation  $\sigma_V \in Q_V$ .

Given any infinite virtually cyclic subgroup  $W \subseteq G$  of type I, we define a preferred generator  $\sigma_W \in Q_W$  as follows. Choose  $g \in G$  and  $V \in \mathcal{S}$  with  $|gWg^{-1} \cap V| = \infty$ . Let  $i_1: gWg^{-1} \cap V \rightarrow W$  be the injection sending  $v$  to  $g^{-1}vg$  and  $i_2: gWg^{-1} \cap V \rightarrow V$  be the inclusion. By Lemma 1.1 (vi) we obtain injections of infinite cyclic groups  $Q_{i_1}: Q_{gWg^{-1} \cap V} \rightarrow Q_W$  and  $Q_{i_2}: Q_{gWg^{-1} \cap V} \rightarrow Q_V$ . Equip  $Q_W$  with the generator  $\sigma_W$  for which there exists integers  $n_1, n_2 \geq 1$  and  $\sigma \in Q_{gWg^{-1} \cap V}$  with  $Q_{i_1}(\sigma) = (\sigma_W)^{n_1}$  and  $Q_{i_2}(\sigma) = (\sigma_V)^{n_2}$ .

We have to show that this is well-defined. Obviously it is independent of the choice of  $\sigma$ ,  $n_1$  and  $n_2$ . It remains to show that the choice of  $g$  does not matter. For this purpose we have to consider the special case  $W = V$  and have to show that the new generator  $\sigma_W$  agrees with the given one  $\sigma_V$ . We conclude from [17, Lemma 4.2] and the argument about the validity of condition (C) appearing in the proof in [17, Theorem 1.1 (ii)] that there exists an infinite cyclic subgroup  $C \subseteq gVg^{-1} \cap V$  such that  $g$  belongs to the normalizer  $N_G C$ . It suffices to show that conjugation with  $g$  induces the identity on  $C$ . Let  $H \subseteq G$  be the subgroup generated by  $g$  and  $C$ . We obtain a short exact sequence  $1 \rightarrow C \rightarrow H \xrightarrow{\text{pr}} H/C \rightarrow 1$ , where  $H/C$  is a cyclic subgroup generated by  $\text{pr}(g)$ . Suppose that  $H/C$  is finite. Then  $H$  is an infinite

virtually cyclic subgroup of  $G$  which must be by assumption of type I. Since the center of  $H$  must be infinite by Lemma 1.1 (ii) and hence the intersection of the center of  $H$  with  $C$  is infinite cyclic, the conjugation action of  $g$  on  $C$  must be trivial. Suppose that  $H/C$  is infinite. Then  $H$  is the fundamental group of the Klein bottle if the conjugation action of  $g$  on  $C$  is non-trivial. Since the fundamental group of the Klein bottle is not a subgroup of  $G$  by assumption, the conjugation action of  $g$  on  $C$  is trivial also in this case.  $\square$

**8.3. Proof of Theorem 0.2.** Let  $\text{Or}_{\mathcal{V}\mathcal{C}_I \setminus \mathcal{F}\text{in}}(G)$  be the full subcategory of the orbit category  $\text{Or}(G)$  consisting of those objects  $G/V$  for which  $V$  is an infinite virtually cyclic subgroup of type I. We obtain a functor

$$\text{gen}(Q?): \text{Or}_{\mathcal{V}\mathcal{C}_I \setminus \mathcal{F}\text{in}}(G) \rightarrow \mathbb{Z}/2\text{-Sets}$$

sending  $G/V$  to  $\text{gen}(Q_V)$ , and a  $G$ -map  $f: G/V \rightarrow G/W$  to  $\text{gen}(f)$  as defined in (6.3). The  $\mathbb{Z}/2$ -action on  $\text{gen}(Q_V)$  is given by taking the inverse of a generator. The condition that the virtually cyclic subgroups of type I of  $G$  are orientable (see Definition 8.5) is equivalent to the condition that the functor  $\text{gen}(Q?)$  is isomorphic to the constant functor sending  $G/V$  to  $\mathbb{Z}/2$ . A choice of an orientation corresponds to a choice of such an isomorphism.

*Proof of Theorem 0.2.* Because of Theorem 0.1 and Lemma 8.4 it suffices to show that the  $\mathbb{Z}[\mathbb{Z}/2]$ -module  $H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}\mathcal{C}_I}(G); \mathbf{NK}_{\mathcal{A}}^G)$  is isomorphic to  $\mathbb{Z}[\mathbb{Z}/2] \otimes_{\mathbb{Z}} A$  for some  $\mathbb{Z}$ -module  $A$ .

Fix an orientation  $\{\sigma_V \mid V \in \mathcal{V}\mathcal{C}_I\}$  in the sense of Definition 8.5. We have the  $\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)$ -spectrum

$$\mathbf{NK}_R^{G'} : \text{Or}_{\mathcal{V}\mathcal{C}_I}(G) \rightarrow \text{Spectra},$$

which sends  $G/V$  to the trivial spectrum if  $V$  is finite and to  $\mathbf{NK}(G/V; \mathcal{A}, \sigma_V)$  if  $V$  is infinite virtually cyclic of type I. This is well-defined by the orientability assumption. Now there is an obvious natural isomorphism of functors from  $\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)$  to the category of  $\mathbb{Z}/2$ -spectra

$$\mathbf{NK}_{\mathcal{A}}^{G'} \wedge (\mathbb{Z}/2)_+ \xrightarrow{\cong} \mathbf{NK}_{\mathcal{A}}^G$$

which is a weak equivalence of  $\text{Or}_{\mathcal{V}\mathcal{C}_I}(G)$ -spectra. It induces an  $\mathbb{Z}[\mathbb{Z}/2]$ -isomorphism

$$H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}\mathcal{C}_I}(G); \mathbf{NK}_{\mathcal{A}}^{G'}) \otimes_{\mathbb{Z}} \mathbb{Z}[\mathbb{Z}/2] \xrightarrow{\cong} H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}\mathcal{C}_I}(G); \mathbf{NK}_{\mathcal{A}}^G).$$

This finishes the proof of Theorem 0.2.  $\square$

## 9. RATIONAL VANISHING OF THE RELATIVE TERM

This section is devoted to the proof of Theorem 0.3.

Consider the following diagram of groups, where the vertical maps are inclusions of subgroups of finite index and the horizontal arrows are automorphisms

$$\begin{array}{ccc} H & \xrightarrow{\phi} & H \\ \downarrow i & & \downarrow i \\ K & \xrightarrow{\psi} & K \end{array}$$

We obtain a commutative diagram

$$(9.1) \quad \begin{array}{ccccc} K_n(RH_{\phi}[t]) & \xrightarrow{i[t]_*} & K_n(RK_{\psi}[t]) & \xrightarrow{i[t]^*} & K_n(RH_{\phi}[t]) \\ \downarrow (\text{ev}_H)_* & & \downarrow (\text{ev}_K)_* & & \downarrow (\text{ev}_H)_* \\ K_n(RH) & \xrightarrow{i_*} & K_n(RK) & \xrightarrow{i^*} & K_n(RH) \end{array}$$

as follows:  $i_*$  and  $i^*$  are the maps induced by induction and restriction with the ring homomorphism  $Ri: RH \rightarrow RK$ ;  $i[t]_*$  and  $i[t]^*$  are the maps induced by induction and restriction with the ring homomorphism  $Ri[t]: RH_\phi[t] \rightarrow RK_\psi[t]$ ;  $\text{ev}_H: RH_\phi[t] \rightarrow RH$  and  $\text{ev}_K: RK_\psi[t] \rightarrow RK$  are the ring homomorphisms given by putting  $t = 0$ .

The left square is obviously well-defined and commutative. The right square is well-defined since the restriction of  $RK$  to  $RH$  by  $Ri$  is a finitely generated free  $RH$ -module and the restriction of  $RK_\psi[t]$  to  $RH_\phi[t]$  by  $Ri[t]$  is a finitely generated free  $RH_\phi[t]$ -module by the following argument.

Put  $l := [K : H]$ . Choose a subset  $\{k_1, k_2, \dots, k_l\}$  of  $K$  such that  $K/H$  can be written as  $\{k_1H, k_2H, \dots, k_lH\}$ . The map

$$\alpha: \bigoplus_{i=1}^l RH \xrightarrow{\cong} i^*RK, \quad (x_1, x_2, \dots, x_l) \mapsto \sum_{i=1}^l x_i \cdot k_i$$

is an homomorphism of  $RH$ -modules and the map

$$\beta: \bigoplus_{i=1}^l RH_\phi[t] \xrightarrow{\cong} i[t]^*RK_\psi[t], \quad (y_1, y_2, \dots, y_l) \mapsto \sum_{i=1}^l y_i \cdot k_i$$

is a homomorphism of  $RH_\phi[t]$ -modules. Obviously  $\alpha$  is bijective. The map  $\beta$  is bijective since for any integer  $m$  we get  $K/H = \{\psi^m(k_1)H, \psi^m(k_2)H, \dots, \psi^m(k_l)H\}$ .

To show that the right square commutes we have to define for every finitely generated projective  $RK_\psi[t]$ -module  $P$  a natural  $RH$ -isomorphism

$$T(P): (\text{ev}_H)_*i[t]^*P \xrightarrow{\cong} i^*(\text{ev}_K)_*P.$$

First we define  $T(P)$ . By the adjunction of induction and restriction it suffices to construct a natural map  $T'(P): i_*(\text{ev}_H)_*i[t]^*P \rightarrow (\text{ev}_K)_*P$ . Since  $i \circ \text{ev}_H = \text{ev}_K \circ i[t]$  we have to construct a natural map  $T''(P): i[t]_*i[t]^*P \rightarrow P$ , since then we define  $T'(P)$  to be  $(\text{ev}_K)_*(T''(P))$ . Now define  $T''(P)$  to be the adjoint of the identity  $\text{id}: i[t]^*P \rightarrow i[t]^*P$ . Explicitly  $T(P)$  sends an element  $h \otimes x$  in  $(\text{ev}_H)_*i[t]^*P = RH \otimes_{\text{ev}_H} i[t]^*P$  to the element  $i(h) \otimes x$  in  $i^*(\text{ev}_K)_*P = RK \otimes_{\text{ev}_K} P$ .

Obviously  $T(P)$  is natural in  $P$  and compatible with direct sums. Hence in order to show that  $T(P)$  is bijective for all finitely generated projective  $RK_\psi[t]$ -modules  $P$ , it suffices to do that for  $P = RK_\psi[t]$ . Now the claim follows since the following diagram of  $RH$ -modules commutes

$$\begin{array}{ccc} RH \otimes_{\text{ev}_H} i[t]^*RK_\psi[t] & \xrightarrow{T(RK_\psi[t])} & i^*(RK \otimes_{\text{ev}_K} RK_\psi[t]) \\ \text{id} \otimes_{\text{ev}_H} \beta \uparrow \cong & & \downarrow \cong \\ RH \otimes_{\text{ev}_H} \left( \bigoplus_{i=1}^l RH_\phi[t] \right) & & i^*RK \\ \cong \uparrow & & \alpha \uparrow \\ \bigoplus_{i=1}^l RH \otimes_{\text{ev}_H} RH_\phi[t] & \xrightarrow{\cong} & \bigoplus_{i=1}^l RH \end{array}$$

where the isomorphisms  $\alpha$  and  $\beta$  have been defined above and all other arrows marked with  $\cong$  are the obvious isomorphisms. Recall that  $NK_n(RH, R\phi)$  is by definition the kernel of  $(\text{ev}_H)_*: K_n(RH_\phi[t]) \rightarrow K_n(RH)$  and the analogous statement holds for  $NK_n(RK, R\psi)$ .

The diagram (9.1) induces homomorphisms

$$\begin{aligned} i_*: NK_n(RH, R\phi) &\rightarrow NK_n(RK, R\psi) \\ i^*: NK_n(RK, R\psi) &\rightarrow NK_n(RH, R\phi) \end{aligned}$$

Since both composites

$$\begin{array}{ccc} K_n(RH_\phi[t]) & \xrightarrow{i[t]^* \circ i[t]_*} & K_n(RH_\phi[t]); \\ K_n(RH) & \xrightarrow{i^* \circ i_*} & K_n(RH), \end{array}$$

are multiplication with  $l$ , we conclude

**Lemma 9.2.** *The composite  $i^* \circ i_* : NK_n(RH, R\phi) \rightarrow NK_n(RH, R\phi)$  is multiplication with  $l$  for all  $n \in \mathbb{Z}$ .*

**Lemma 9.3.** *Let  $\phi : K \rightarrow K$  be an inner automorphism of the group  $K$ . Then there is for all  $n \in \mathbb{Z}$  an isomorphism*

$$NK_n(RK, R\phi) \xrightarrow{\cong} NK_n(RK).$$

*Proof.* Let  $k$  be an element such that  $\phi$  is given by conjugation with  $k$ . We obtain a ring isomorphism

$$\eta : RK_{R\phi}[t] \xrightarrow{\cong} RK[t], \quad \sum_i \lambda_i t^i \mapsto \sum_i \lambda_i k^i t^i.$$

Let  $\text{ev}_{RK, \phi} : RK_\phi[t] \rightarrow RK$  and  $\text{ev}_{RK} : RK[t] \rightarrow RK$  be the ring homomorphisms given by putting  $t = 0$ . Then we obtain a commutative diagram with isomorphisms as vertical arrows

$$\begin{array}{ccc} K_n(RK_{R\phi}[t]) & \xrightarrow[\cong]{\eta} & K_n(RK[t]) \\ \downarrow \text{ev}_{RK, \phi} & & \downarrow \text{ev}_{RK} \\ K_n(RK) & \xrightarrow[\text{id}]{\cong} & K_n(RK) \end{array}$$

It induces the desired isomorphism  $NK_n(RK, R\phi) \xrightarrow{\cong} NK_n(RK)$ .  $\square$

*Remark.* As the referee has pointed out, this result holds more generally (with identical proof) for the twisted Bass' group  $NF(S, \phi)$  of any functor  $F$  from rings to abelian groups and any inner ring automorphism  $\phi : S \rightarrow S$ .

**Theorem 9.4.** *Let  $R$  be a regular ring. Let  $K$  be a finite group of order  $r$  and let  $\phi : K \xrightarrow{\cong} K$  be an automorphism of order  $s$ .*

*Then  $NK_n(RK, R\phi)[1/rs] = 0$  for all  $n \in \mathbb{Z}$ . In particular  $NK_n(RK, R\phi) \otimes_{\mathbb{Z}} \mathbb{Q} = 0$  for all  $n \in \mathbb{Z}$ .*

*Proof.* Let  $t$  be a generator of the cyclic group  $\mathbb{Z}/s$  of order  $s$ . Consider the semi-direct product  $K \rtimes_{\phi} \mathbb{Z}/s$ . Let  $i : K \rightarrow K \rtimes_{\phi} \mathbb{Z}/s$  be the canonical inclusion. Let  $\psi$  be the inner automorphism of  $K \rtimes_{\phi} \mathbb{Z}/s$  given by conjugation with  $t$ . Then  $[K \rtimes_{\phi} \mathbb{Z}/s : K] = s$  and the following diagram commutes

$$\begin{array}{ccc} K & \xrightarrow{\phi} & K \\ \downarrow i & & \downarrow i \\ K \rtimes_{\phi} \mathbb{Z}/s & \xrightarrow{\psi} & K \rtimes_{\phi} \mathbb{Z}/s \end{array}$$

Lemma 9.2 and Lemma 9.3 yield maps  $i_* : NK_n(RK, \phi) \rightarrow NK_n(R[K \rtimes_{\phi} \mathbb{Z}/s])$  and  $i^* : NK_n(R[K \rtimes_{\phi} \mathbb{Z}/s]) \rightarrow NK_n(RK, \phi)$  such that  $i^* \circ i_* = s \cdot \text{id}$ . This implies that  $NK_n(RK, \phi)[1/s]$  is a direct summand in  $NK_n(R[K \rtimes_{\phi} \mathbb{Z}/s])[1/s]$ . Since  $R$  is regular by assumption and hence  $NK_n(R)$  vanishes for all  $n \in \mathbb{Z}$ , we conclude from [14, Theorem A]

$$NK_n(R[K \rtimes_{\phi} \mathbb{Z}/s])[1/rs] = 0.$$

(For  $R = \mathbb{Z}$  and some related rings, this has already been proved by Weibel [25, (6.5), p. 490].) This implies  $NK_n(RK, \phi)[1/rs] = 0$ .  $\square$

Theorem 9.4 has already been proved for  $R = \mathbb{Z}$  in [13, Theorem 5.11].

Now we are ready to give the proof of Theorem 0.3.

*Proof of Theorem 0.3.* Because of Theorem 0.1 it suffices to prove for all  $n \in \mathbb{Z}$

$$H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_R^G) \otimes_{\mathbb{Z}} \mathbb{Q} \xrightarrow{\cong} \{0\}.$$

There is a spectral sequence converging to  $H_{p+q}^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_R^G)$  whose  $E^2$ -term is the Bredon homology

$$E_{p,q}^2 = H_p^{\mathbb{Z}\text{Or}_{\mathcal{V}C_I}(G)}(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \pi_q(\mathbf{NK}_R^G))$$

with coefficients in the covariant functor from  $\text{Or}_{\mathcal{V}C_I}(G)$  to the category of  $\mathbb{Z}$ -modules coming from composing  $\mathbf{NK}_R^G: \text{Or}_{\mathcal{V}C_I}(G) \rightarrow \text{Spectra}$  with the functor taking the  $q$ -homotopy group (see [5, Theorem 4.7 and Theorem 7.4]). Since  $\mathbb{Q}$  is flat over  $\mathbb{Z}$ , it suffices to show for all  $V \in \mathcal{V}C_I$

$$\pi_q(\mathbf{NK}_R^G(G/V)) \otimes_{\mathbb{Z}} \mathbb{Q} = 0$$

If  $V$  is finite,  $\mathbf{NK}_R^G(G/V)$  is by construction the trivial spectrum and the claim is obviously true. If  $V$  is a virtually cyclic group of type I, then we conclude from the diagram (5.6)

$$\pi_n(\mathbf{NK}_R^G(G/V)) \cong NK_n(RK_V, R\phi) \oplus NK_n(RK_V, R\phi^{-1}).$$

Now the claim follows from Theorem 9.4.  $\square$

## 10. ON THE COMPUTATION OF THE RELATIVE TERM

In this section we give some further information about the computation of the relative term  $H_n^G(\underline{E}G \rightarrow \underline{E}G; \mathbf{K}_R^G) \cong H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C}(G); \mathbf{NK}_R^G)$ .

In [21] one can find a systematic analysis how the space  $E_{\mathcal{V}C_I}(G)$  is obtained from  $\underline{E}G$ . We say that  $G$  satisfies the condition  $(M_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$  if any virtually cyclic subgroup of type I is contained in a unique maximal infinite cyclic subgroup of type I. We say that  $G$  satisfies the condition  $(NM_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$  if it satisfies  $(M_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$  and for any maximal virtually cyclic subgroup  $V$  of type I its normalizer  $N_G V$  agrees with  $V$ . Every word hyperbolic group satisfies  $(NM_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$ , see [21, Example 3.6].

Suppose that  $G$  satisfies  $(M_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V}C_I})$ . Let  $\mathcal{M}$  be a complete system of representatives  $V$  of the conjugacy classes of maximal virtually cyclic subgroups of type I. Then we conclude from [21, Corollary 2.8] that there exists a  $G$ -pushout of  $G$ -CW-complexes with inclusions as horizontal maps

$$\begin{array}{ccc} \coprod_{V \in \mathcal{M}} G \times_{N_G V} \underline{E}N_G V & \xrightarrow{i} & \underline{E}G \\ \downarrow \coprod_{V \in \mathcal{M}} \text{id}_G \times f_V & & \downarrow f \\ \coprod_{V \in \mathcal{M}} G \times_{N_G V} E_{\mathcal{V}C_I}(N_G V) & \longrightarrow & E_{\mathcal{V}C_I}(G) \end{array}$$

This yields for all  $n \in \mathbb{Z}$  an isomorphism using the induction structure in the sense of [15, Section 1]

$$\bigoplus_{V \in \mathcal{M}} H_n^{N_G V}(\underline{E}N_G V \rightarrow E_{\mathcal{V}C_I}(N_G V); \mathbf{K}_R^{N_G V}) \xrightarrow{\cong} H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{K}_R^G).$$

Combining this with Theorem 0.1 yields the isomorphism

$$\bigoplus_{V \in \mathcal{M}} H_n^{N_G V}(\underline{E}N_G V \rightarrow E_{\mathcal{V}C_I}(N_G V); \mathbf{NK}_R^{N_G V}) \xrightarrow{\cong} H_n^G(\underline{E}G \rightarrow E_{\mathcal{V}C_I}(G); \mathbf{NK}_R^G).$$

Suppose now that  $G$  satisfies  $(NM_{\mathcal{F}_{\text{in}} \subseteq \mathcal{V} \mathcal{C}_I})$  and recall that, by definition,  $NK_R^G(V/H) = 0$  for finite  $H$ . Then the isomorphism above reduces to the isomorphism

$$\bigoplus_{V \in \mathcal{M}} \pi_n(\mathbf{NK}_R^V(V/V)) \xrightarrow{\cong} H_n^G(\underline{E}G \rightarrow E_{\mathcal{V} \mathcal{C}_I}(G); \mathbf{K}_R^G),$$

and  $\pi_n(\mathbf{NK}_R^V(V/V))$  is the Nil-term  $NK_n(RK_V, R\phi) \oplus NK_n(RK_V; R\phi^{-1})$  appearing in the twisted version of the Bass-Heller-Swan-decomposition of  $RV$  (see [11, Theorem 2.1 and Theorem 2.3]) if we write  $V \cong K_V \rtimes_{\phi} \mathbb{Z}$ .

## 11. FIBERED VERSION

We illustrate in this section by an example which will be crucial in [9] that we do get information from our setting also in a fibered situation.

Let  $p: X \rightarrow B$  be a map of path connected spaces. We will assume that it is  $\pi_1$ -surjective, i.e., induces an epimorphism on fundamental groups. Suppose that  $B$  admits a universal covering  $q: \tilde{B} \rightarrow B$ .

Choose base points  $x_0 \in X$ ,  $b_0 \in B$  and  $\tilde{b}_0 \in \tilde{B}$  satisfying  $p(x_0) = b_0 = q(\tilde{b}_0)$ . We will abbreviate  $\Gamma = \pi_1(X, x_0)$  and  $G = \pi_1(B, b_0)$ . Recall that we have a free right proper  $G$ -action on  $\tilde{B}$  and  $q$  induces a homeomorphism  $\tilde{B}/G \xrightarrow{\cong} B$ . For a subgroup  $H \subseteq G$  denote by  $q(G/H): \tilde{B} \times_G G/H = \tilde{B}/H \rightarrow B$  the obvious covering induced by  $q$ . The pullback construction yields a commutative square of spaces

$$\begin{array}{ccc} X(G/H) & \xrightarrow{\bar{q}(G/H)} & X \\ \bar{p}(G/H) \downarrow & & \downarrow p \\ \tilde{B} \times_G G/H & \xrightarrow{q(G/H)} & B \end{array}$$

where  $\bar{q}(G/H)$  is again a covering. This yields covariant functors from the orbit category of  $G$  to the category of topological spaces

$$\begin{aligned} \underline{B}: \text{Or}(G) &\rightarrow \text{Spaces}, & G/H &\rightarrow \tilde{B} \times_G G/H; \\ \underline{X}: \text{Or}(G) &\rightarrow \text{Spaces}, & G/H &\rightarrow X(G/H). \end{aligned}$$

The assumption that  $p$  is  $\pi_1$ -surjective ensures that  $X(G/H)$  is path connected for all  $H \subseteq G$ .

By composition with the fundamental groupoid functor we obtain a functor

$$\underline{\Pi}(X): \text{Or}(G) \rightarrow \text{Groupoids}, \quad G/H \mapsto \Pi(X(G/H))$$

Let  $R$ -FGF be the additive category whose set of objects is  $\{R^n \mid n = 0, 1, 2, \dots\}$  and whose morphisms are  $R$ -linear maps. In the sequel it will always be equipped with the trivial  $G$  or  $\Gamma$ -action or considered as constant functor  $\mathcal{G} \rightarrow \text{Add-Cat}$ . Consider the functor

$$\xi: \text{Groupoids} \rightarrow \text{Spectra}, \quad \mathcal{G} \mapsto \mathbf{K} \left( \int_{\mathcal{G}} R\text{-FGF} \right).$$

The composite of the last two functors yields a functor

$$\mathbf{K}(p) := \xi \circ \underline{\Pi}(X): \text{Or}(G) \rightarrow \text{Spectra}.$$

Associated to this functor there is a  $G$ -homology theory  $H_*^G(-; \mathbf{K}(p)) := \pi_n(O^G(-) \wedge_{\text{Or}(G)} \mathbf{K}(p))$  (see [5]). We will be interested in the associated assembly map induced by the projection  $\underline{E}G \rightarrow G/G$ ,

$$(11.1) \quad H_n^G(\underline{E}G; \mathbf{K}(p)) \rightarrow H_n^G(G/G; \mathbf{K}(p)) \cong K_n(R\Gamma).$$

The goal of this section is to identify this assembly map with the assembly map

$$H_n^G(\underline{EG}; \mathbf{K}_{\mathcal{A}}) \rightarrow H_n^G(G/G; \mathbf{K}_{\mathcal{A}}) = K_n(R\Gamma)$$

for a suitable additive category with  $G$ -action  $\mathcal{A}$ . Thus the results of this paper apply also in the fibered setup.

Consider the following functor

$$\underline{\mathcal{G}}^\Gamma: \text{Or}(G) \rightarrow \text{Groupoids}, \quad G/H \rightarrow \mathcal{G}^\Gamma(G/H),$$

where we consider  $G/H$  as a  $\Gamma$ -set by restriction along the group homomorphism  $\Gamma \rightarrow G$  induced by  $p$ .

**Lemma 11.2.** *There is a natural equivalence*

$$T: \underline{\mathcal{G}}^\Gamma \rightarrow \underline{\Pi}(X)$$

of covariant functors  $\text{Or}(G) \rightarrow \text{Groupoids}$ .

*Proof.* Given an object  $G/H$  in  $\text{Or}(G)$ , we have to specify an equivalence of groupoids  $T(G/H): \mathcal{G}^\Gamma(G/H) \rightarrow \Pi(X(G/H))$ . For an object in  $\mathcal{G}^\Gamma(G/H)$  which is given by an element  $wH \in G/H$ , define  $T(wH)$  to be the point in  $X(G/H)$  which is determined by  $(\tilde{b}_0, wH) \in \tilde{B} \times_G G/H$  and  $x_0 \in X$ . This makes sense since  $q(G/H)((\tilde{b}_0, wH)) = b_0 = q(x_0)$ .

Let  $\gamma: w_0H \rightarrow w_1H$  be a morphism in  $\mathcal{G}^\Gamma(G/H)$ . Choose a loop  $u_X$  in  $X$  at  $x_0 \in X$  which represents  $\gamma$ . Let  $u_B$  be the loop  $p \circ u_X$  in  $B$  at  $b_0 \in B$ . There is precisely one path  $u_{\tilde{B}}$  in  $\tilde{B}$  which starts at  $\tilde{b}_0$  and satisfies  $q \circ u_{\tilde{B}} = u_B$ . Let  $[u_B] \in G$  be the class of  $u_B$ , or, equivalently, the image of  $\gamma$  under  $\pi_1(p, x_0): \Gamma \rightarrow G$ . By definition of the right  $G$ -action on  $\tilde{B}$  we have  $\tilde{b}_0 \cdot [u_B] = u_B(1)$ . Define a path  $u_{\tilde{B}/H}$  in  $\tilde{B} \times_G G/H$  from  $(\tilde{b}_0, w_0H)$  to  $(\tilde{b}_0, w_1H)$  by  $t \mapsto (u_B(t), w_0H)$ . This is indeed a path ending at  $(\tilde{b}_0, w_1H)$  since  $(\tilde{b}_0 \cdot [u_B], w_0H) = (\tilde{b}_0, [u_B] \cdot w_0H) = (\tilde{b}_0, w_1H)$  holds in  $\tilde{B} \times_G G/H$ . Obviously the composite of  $u_{\tilde{B}/H}$  with  $q(G/H): \tilde{B} \times_G G/H \rightarrow B$  is  $u_B$ . Hence  $u_{\tilde{B}/H}$  and  $u_X$  determine a path in  $X(G/H)$  from  $T(w_0H) \rightarrow T(w_1H)$  and hence a morphism  $T(w_0H) \rightarrow T(w_1H)$  in  $\Pi(X(G/H))$ . One easily checks that the homotopy class (relative to the endpoints) of  $u$  depends only on  $\gamma$ . Thus we obtain the desired functor  $T(G/H): \mathcal{G}^\Gamma(G/H) \rightarrow \Pi(X(G/H))$ . One easily checks that they fit together so that we obtain a natural transformation  $T: \underline{\mathcal{G}}^\Gamma \rightarrow \underline{\Pi}(X)$ .

At a homogeneous space  $G/H$ , the value of  $\underline{\mathcal{G}}^\Gamma$  is a groupoid equivalent to the group  $\pi_1(p, x_0)^{-1}(H)$  while the value of  $\underline{\Pi}(X)$  is a groupoid equivalent to the fundamental group of  $X(G/H)$ . Up to this equivalence, the functor  $T$ , at  $G/H$ , is the standard identification of these two groupoids. Hence  $T$  is a natural equivalence.  $\square$

We obtain a covariant functor

$$\mathbf{K}(p)': \text{Or}(G) \rightarrow \text{Spectra}, \quad G/H \mapsto \mathbf{K} \left( \int_{\mathcal{G}^\Gamma(G/H)} R\text{-FGF} \right).$$

Lemma 11.2 implies that the following diagram commutes where the vertical arrow is the isomorphism induced by  $T$ .

$$\begin{array}{ccc}
 H_n^G(\underline{EG}; \mathbf{K}(p)) & \xrightarrow{H_n^G(\text{pr}; \mathbf{K}(p))} & H_n^G(G/G; \mathbf{K}(p)) = K_n(R\Gamma) \\
 \uparrow T_* \cong & & \uparrow \\
 H_n^G(\underline{EG}; \mathbf{K}(p)') & \xrightarrow{H_n^G(\text{pr}; \mathbf{K}(p)')} & 
 \end{array}$$

Now the functor  $\mathbf{K}(p)'$  is, up to natural equivalence, of the form  $\mathbf{K}_{\mathcal{A}}^G$  for some additive  $G$ -category, namely for  $\mathcal{A} = \text{ind}_q: \Gamma \rightarrow_G R\text{-FGF}$ , see [1, (11.5) and Lemma 11.6]. We conclude

**Lemma 11.3.** *The assembly map (11.1) is an isomorphism for all  $n \in \mathbb{Z}$ , if the  $K$ -theoretic Farrell-Jones Conjecture for additive categories holds for  $G$ .*
